tion, the ability of the castrated rats to go into estrus and the potency of the follicular hormone were tested in the following manner. Urine from a pregnant woman was extracted and the concentrate injected into a group of four rats, according to Kurzrok's⁸ technique. In forty-eight hours, estrual changes were demonstrable by means of a vaginal smear in the whole group. Three doses of 5 rat units of the follicular hormone were then injected into each of another group of four rats, and all these also showed estrual changes. The effect of larger doses of the ovarian follicular hormone on the clotting time of the blood is shown in table 3.

During the thirteen day period that the hormone was injected, specimens of twenty-four hour urine were collected daily and assayed for the presence of the estrogenic substance. The same groups of animals were used repeatedly for the tests because, according to Allen and Doisy⁹ and Kurzrok¹⁰ the hormone when injected parenterally induces only one estrual cycle.

At no time during this period was there any evidence of estrus in any of the animals; in other words we were not able to recover the injected hormone. This observation is in accordance with Frank¹² who found that the injection of 5,000 mouse units subcutaneously had no demonstrable effect on the amount recoverable

TABLE 3—The Effect of Larger Doses of Follicular Hormone and Direct Blood Transfusion on the Coagulation Time of the Blood

	Date	Coagulation Time
Ovarian follicular hormone 50 rat units intramuscularly daily	3/14/33	72 minutes
Ovarian follicular hormone 100 rat units intramuscularly daily	3/16/33 3/19/33 3/21/33	7 minutes 7 minutes 42 minutes
Hemarthrosis left knee joint	3/22/33 3/23/33 3/24/33	7 minutes 7 minutes 72 minutes
Ovarian hormone discontinued	3/26/33 3/27/33	40 minutes
Direct blood transfusion 200 cc of whole blood	3/1/33 3/2/33	21 minutes

from the urine of a normal woman.¹¹ The Council on Pharmacy and Chemistry of the American Medical Association¹³ suggests that the possibility of inactivation or destruction of the hormone by or in the tissues should be considered.

We should like to call attention to the effect of whole blood transfusion on the coagulation time. One day after the transfusion the clotting time dropped to twenty-one minutes, almost to a normal level. This effect, of course, was only temporary. During the administration of the hormone, no untoward reactions were observed in our hemophiliac patient. However, in the literature there are warnings against the indiscriminate use of the estrogenic substance. Kunde, D'Amour, Gustafson and Carlson¹⁴ have shown that in young rats bodily growth rate is reduced and the testes or ovaries are markedly smaller than normal after prolonged administration of this substance. Also Cook and Dodds¹⁵ have demonstrated that pure synthetic compounds of known molecular structure can possess both estrogenic and carcinogenic properties. Moreover, the use of these hormones may give rise to a false sense of security, and some conceivably older proved measures to combat the disease are apt to be neglected.

CONCLUSIONS

1 Our work does not support the theory of the close relationship of the female sex hormone to hemophilia. (a) We have not been able to demonstrate the presence of the estrogenic substance in the urine of normal males. If the female sex hormone holds hemophilia in abeyance it should be present in the urine of all normal males rather than in isolated cases. (b) The commercial estrogenic substance employed by us of known potency, failed to reduce the coagulation time of the blood or stop the several hemorrhages in our hemophiliac patient.

2 It would seem that symptomatic treatment and blood transfusions are still the methods of choice in hemophilia.

ARGYRIA

REPORT OF TWO CASES IN CHILDREN

HUGH K. BERKLEY, M.D., LOS ANGELES

It is a matter of common knowledge that the continued oral use of silver salts may lead to the production of argyria. Formerly silver preparations were widely used in the treatment of certain diseases of the gastrointestinal tract and of the nervous system. Because of the occasional production of argyria the oral administration of silver has been largely discontinued.

Newer preparations of silver have opened other avenues for its use in the treatment of various conditions. At present various forms of colloidal silver enjoy a widespread usage in infections of the eye and of the upper respiratory tract.

Attention has recently been called to the fact that the silver content of some of these newer preparations is not always evident from their proprietary names.¹ It was further pointed out that the younger generation of physicians may not be familiar with argyria. Both of these facts are undoubtedly true. It should be added that self-medication for colds is a very common practice. A preparation prescribed by a physician may be used by the patient for every subsequent similar illness without the knowledge or consent of the physician and long after his connection with the case has ceased. In this way certain silver preparations have come to occupy a prominent place among household remedies. They are used not only in the treatment of common colds but also as an interim prophylactic measure against colds.

Royster² reported a case of argyria in a 5½ year old child produced by nasal irrigations of large amounts of neosilvol.

Woodward³ recently reported three cases in children all from the intranasal use of neosilvol. He particularly stressed the continued use of the preparation first introduced by a physician's prescription.

The following two cases of argyria are the result of the indiscriminate use of this drug.

CASE 1—B. P., a girl aged 10 years, admitted to the Children's Hospital Dec. 24, 1932, in the service of Dr. Victor E. Storl, was the only child of healthy parents. She had had chickenpox, measles and pertussis. Otherwise the history was irrelevant. She complained of pain in the head and nausea. Two years before, the child began to have frequent colds and a sinus infection associated with an excessive nasal discharge. For several months she had been treated by a nose and throat specialist. At this time there developed a pain in the head associated with a high fever. A diagnosis of mastoiditis and

³ Woodward, W. R. Argyria from the Use of Colloidal Silver Iodide Intranasally. Am. J. Dis. Child. 45:1046 (May) 1933.

frontal sinusitis was made and she was operated on in July 1931. One week later very severe headaches developed and an exploratory decompression was done. Nothing was found. Since this operation the child had had three convulsive seizures, preceded by a severe right-sided headache and lasting from fifteen to twenty minutes. She was frequently nauseated and occasionally vomited.

During this two year illness the patient had nasal drops of neosilvol two or three times daily. There was no history of the administration of other medication.

The patient was well developed and not acutely ill. The skin was of a dusky slate color and was very striking in appearance. The grayish discoloration was most marked over the hard palate and the exposed surfaces of the body. The color was accentuated under the eyes and about the lips and nose. The scleræ showed a very definite slate color. The buccal mucous membranes and those of the eyes were of normal color. The finger nails and toe nails were normally pink. The covered portions of the extremities and trunk showed little discoloration.

There was a scar over the right parietal region from a decompression operation. Scars were present over the right mastoid region and above the right eye.

The heart was of normal size and the heart sounds were clear. The lungs were clear and the remainder of the physical examination was entirely negative. The urine was normal except for an occasional epithelial cell and pus cells.

A blood count showed hemoglobin, 91 per cent (Sahli), red blood cells, 5,490,000; white blood cells, 7,650, with 68 per cent neutrophils, 28 per cent lymphocytes, 2 per cent eosinophils and 2 per cent basophils. The blood pressure was 118 systolic, 85 diastolic.

The intradermal tuberculin test with 0.1 mg. of old tuberculin was negative after forty-eight hours. The Wassermann and Kahn tests were negative.

The diagnosis was epilepsy and argyria.

Several subsequent hospital admissions have definitely established the diagnosis of epilepsy. The discoloration of the skin has increased materially.

CASE 2—V. F., a girl aged 7 years was brought to the office for general examination because of poor color, dark circles under the eyes, anorexia and nervousness.

The father, mother and 4 year old brother were living and well.

The patient had had frequent attacks of tonsillitis up to 3 years of age when the tonsils and adenoids were removed. There was considerable improvement for one year and then she again had frequent sore throats and colds. She had had acute otitis at 1 year and pyuria at 3 years. She had mumps but no other childhood disease.

When the patient was 8 months of age a 15 per cent solution of neosilvol was prescribed for intranasal use. This preparation was used daily until the tonsils were removed at 3 years. After she was 4 years of age it was again used on an average of from three to five days in each month up to the present time (March 30, 1933).

The patient was rather thin and did not appear acutely ill. There was a well marked bluish discoloration of the skin under the eyes and at the side of the nose. The entire face had a slight bluish tinge. The color of the extremities and trunk appeared normal. The tonsillar fossae were clean. The heart and lungs were normal. The remainder of the examination was entirely negative.

The diagnosis was undernutrition and argyria.

Both of these cases have been seen by a number of physicians and the diagnosis of argyria is undisputed in each case.

Neosilvol is stated by the manufacturer to be "20 per cent of silver iodide in a state of colloidal subdivision combined with a soluble protein base." While these cases and the cases reported by Royster and Woodward occurred on this one preparation it seems certain that other salts of a similar nature could produce the same result if similarly used. The fact that neosilvol does not stain so markedly as other preparations may account for its more frequent use.

The collection of six cases of argyria occurring in widely separated localities and in a period of less than one year leads one to suspect that the condition is not infrequent. Doubtless many of the milder cases are entirely overlooked.

CONCLUSIONS

Colloidal silver preparations used intranasally can produce argyria.

The unsightliness and the irremediable character of the condition make it imperative that physicians exercise more care in the use of these preparations and that they warn their patients against frequent or continuous usage.

ANORECTAL MELANOMA

A. W. MARTIN MARINO, M.D., BROOKLYN

Instructor in Surgery, Long Island College of Medicine

Primary melanoma of the anus or rectum is extremely rare. The name is derived from its color, which is due to a deposit of the pigment melanin, which is essentially of metabolic origin. Frequently a secondary pigmentation occurs from the absorption of extravasated blood. Ewing¹ defines this condition as follows: "Melanoma is a pigmentiferous tumor arising from a specific mesoblastic cell, the chromatophore, and possibly also from epithelial cells which have been modified by pigment production." He further states that "Virchow recognized both a sarcomatous and a carcinomatous melanoma, the former exhibiting a diffuse structure of spindle cells, the latter an alveolar structure and he employed the term 'melanoma' for the entire group." Its growth is much more rapid than carcinoma and it produces early metastases through the blood current. Secondary rectal invasion is not infrequent, owing to metastases from the original growth in other pelvic organs.

Chalier and Bonnet,² in addition to one personal case collected and reviewed from the literature sixty-four tumors of the melanotic variety and estimated that they represented 66 per cent of all rectal sarcomas and that they formed from 2 to 3 per cent of all melanotic growths in the body.

Weeks³ reports one case of large spindle cell sarcoma and states that a review of the literature revealed 100 cases of sarcoma of the rectum. He further says: "In 200 cases of malignant disease of the rectum, carcinoma is found approximately 199 times and sarcoma once. Of the rectal sarcomas the melanotic type is twice as frequent as are the other varieties." This statement is well borne out by Kallet and Saltzstein⁴ who reported seven cases of malignant disease of the rectum three of which were melanomas and the remainder consisted of two cases of spindle-cell sarcoma, and one case each of myosarcoma and lymphosarcoma.

Allen⁵ recently reported a case of melanotic carcinoma of the anorectal region. At first sight his patient's condition somewhat resembled a thrombotic hemorrhoid.

Brick⁶ reported that he saw only one case in a person, aged 62, the nature of the growth was unsuspected before operation.

Jones⁷ wrote that melanotic carcinoma had not been reported once in 300 cases by his pathologist and that sarcoma was not found once in 300 cases from which specimens were examined.

The following case is reported because of the rarity of the condition and also because of the possibility of confusing these tumors with thrombosed hemorrhoids.

REPORT OF CASE

History—Mrs. E. H., aged 62, born in the United States, white, a housewife, admitted to the Brooklyn Hospital July 15, 1931, complained of hemorrhoids, pain accompanying defecation, anorectal protrusion and rectal discharge and bleeding.

About ten months before admission she began to have pain on defecation. The pain gradually and progressively increased.

From the Surgical Service, Division of Proctology, the Brooklyn Hospital, Dr. Ernest K. Tanner, chief attending surgeon.

4. Kallet, H. I. and Saltzstein, H. C. *Sarcoma Melanoma Icyko sarcoma of the Rectum*. *Tr. Am. Proct. Soc.* 33, 75-84, 1932.

5. Allen, A. K. *Melanotic Carcinoma of the Anus*. *Tr. Am. Proct. Soc.* 32, 31, 1931.

6. Brick, J. C. *Malignant Tumors of the Rectum*. In Cooke, A. B. *A Treatise on Diseases of the Rectum*. Philadelphia: F. A. Davis Company, 1914, chapter XXX, p. 58.

7. Jones, D. F. *Malignant Disease of the Rectum*. In *Johns and Jones' Lectures on Surgery*, vol. 5, chapter IX, p. 224.

so that at the time of admission it was quite distressing. Four months after the onset of the present trouble she noticed a rectal protrusion, which became more marked at the time of defecation. There was a mucous discharge present from the onset and bleeding at defecation for one week before admission.

She stated that her general health always had been good. There were no urinary nor digestive disturbances and there was no loss of weight but she had noticed a tendency to constipation, which yielded to magnesium magma.

Examination—The patient was well developed and well nourished. She was not acutely ill but rather apprehensive in anticipation of the examination. The general physical examination was essentially negative excepting for a blood pressure of 180 systolic with 100 diastolic. The urine was normal.

Anorectal examination revealed an ovoid mass about 2 by 3 cm. located in the anterior anorectal region, the greater part of the mass arising from the anal region. It had the appearance and color of an unusually large gangrenous thrombosed hemorrhoid with a very thin covering. A foul smelling mucopurulent discharge was present. The sphincter was found spastic, but there was no anal constriction on digital examination. No masses nor induration were felt in the rectum. On proctoscopic examination there were no ulcerations nor neoplasms found in either the rectum or the sigmoid but on anoscopy the mass described could be seen arising from the anterior anorectal region, more on the anal side.

Operation—Under spinal anesthesia 50 mg. of procaine hydrochloride being used wide crater resection of the mass with cauterization of the base was performed July 16 the day following admission.

A pathologic report was made by James Denton.

Gross—A globular mass about 2 cm. in diameter was smooth, reddish black, and apparently covered with mucous membrane or anal skin on more than half of the surface. On section it was solid and blackish red.

Histologic—Section showed a cellular melanoma of the epithelial type making up most of the bulk of the mass. There was a rather scanty stroma and in this there were numerous melanin granules.

A diagnosis of melanoma of the anus was made.

Postoperative Course—The patient's temperature ranged between 98 and 98.2 F., the pulse rate between 65 and 75, and the respirations remained at 20.

The patient was catheterized eighteen hours after operation and voided voluntarily after that. The bowels moved on the third postoperative day and regularly thereafter.

The wound was dressed and cleansed daily, and on July 22, the fifth postoperative day, the anorectal region appeared satisfactory, and she was discharged. The wound was again dressed, July 25 and 29, and on August 3 at the last visit, the wound was entirely healed. At a follow-up examination, September 4, no evidence of the tumor was found locally and no recognizable metastases could be found after careful examination. Radiotherapy was not tried because melanomas are notoriously radioresistant. The intravenous administration of lead was not employed for the reason that the danger of lead poisoning would be introduced, and its use has been followed by little if any benefit in these cases.

On November 1 she noticed a small lump in the right groin, and by Jan. 23, 1932, although there was no local recurrence, it was found that the mass in the groin, now purplish black, had grown to the size of a lemon.

Further active treatment would have been an added burden to the patient and relatives. She died, June 24.

COMMENT

1 In a case of primary melanoma of the anus with rectal involvement, although metastases were not recognizable before operation, they were present or stimulated as proved by their rapid appearance following the resection.

2 All tissues excised from the anorectal region should be examined histologically.

3 Melanomas metastasize early and rapidly. Excision and examination of apparently insignificant small masses are suggested as prophylactic measures.

CLINICAL CONTROL OF CHRONIC HEMORRHAGIC STATES IN CHILDHOOD

I. NEWTON KUGELMASS, MD
NEW YORK

Rational procedures for arresting hemorrhage are of ancient heritage. Homer relates with pride many of our current methods then applied to bleeding gods and fallen heroes of Greek mythology. While these methods were more effective for the inanimate gods than for the human heroes, the same therapeutic attempts still remain routine. Hippocrates (400 B. C.) applied styptics, ice, compression and elevation with better reasoning than result in the treatment of bleeding wounds. Celsus (20 A. D.) introduced cauterization, excision and ligature as surgical means of treating hemorrhage.

Fig. 1—Constitution, heredity—endocrine, allergic. The hemorrhagic status of a patient. Equilibrium between reticulo endothelial system, vascular endothelium and tissues affected by endogenous and exogenous factors.

But these procedures were used only in emergencies because bleeding was considered an earthly means of bodily purification. Local measures of treating hemorrhage persisted until the nineteenth century, when Blundell (1824) first transfused man from a human donor. Thus did a whole century pass before the therapeutic value of transfusion was turned from the metaphysical speculation of rejuvenation to rational physiology. It was not until 1860, when Alexander Schmitt studied the mechanism of blood coagulation that new approaches developed in the diagnosis and treatment of hemorrhagic disturbances.

Hemorrhagic states are unitary and unique. Their manifestations are as individual as the particular patient, as varied as the determining disease, and as widespread as are the offended organs and tissues. And yet they show few symptoms and fewer signs to be ever adequate for diagnostic differentiation without

further scientific study. The more accustomed one is to seeking similarities in the diagnosis of disease, the more is one eluded in attempts at patterning pictures of hemorrhagic diversities. The hemorrhagic state is a many dimensional portrait rather than a two dimensional textbook picture. Confronted with a hemorrhagic problem one must confuse neither the site nor the severity of bleeding with a specific hemorrhagic

Fig. 2—The clotting mechanism

state. In no field of medicine is clinical judgment more exacting than in the interpretation of hematologic observations. Effective control of hemorrhagic states—potential or active—depends on simple therapeutic measures, once diagnostic specificity has been determined.

Hematologic studies of children presenting hemorrhagic symptoms have greatly minimized the number of true hemorrhagic diseases. In a sequential series of 5,000 sick children observed in three hospitals in the city, 7 per cent showed hemorrhagic symptomatology. But out of the 325 cases involving bleeding symptoms, only 95 proved to be veritable hemorrhagic diseases with abnormal deviations in the blood-clotting constituents. While these children showed more marked and more persistent bleeding than those with nonhemorrhagic diseases, the sites of bleeding were no different. Localized hemorrhages were more frequently the result of systemic disease than of local injury, and marked multiple hemorrhages usually revealed active hemorrhagic disease. Spontaneous bleeding was more prevalent than the traumatic and more difficult to control. In new-born infants it was the consequence of non-hemorrhagic disease, while in children spontaneous bleeding was precipitated by active hemorrhagic disease. Bleeding symptoms predominated among boys with true hemorrhagic diseases and among girls with nonhemorrhagic diseases, and a family history of a bleeding tendency was obtained in both groups. The majority of hemorrhagic problems were observed in older children, but control of hemorrhages was more effectively obtained in younger children in whom mild bleeding manifestations resulted in early hematologic diagnosis. And yet recovery from very severe injury to the reticulo-endothelial system has been witnessed at all ages. The more hemorrhagic problems are studied, the more atypical and transitional they behave in comparison with classic descriptions. Hemorrhagic states ever require individual study for diagnostic certainty.

ESSENTIAL DIAGNOSTIC PROCEDURES FOR
HEMORRHAGIC DISTURBANCES

Hemorrhagic symptomatology rarely reveals the clinical diagnosis. Methods have been devised for the study of the actual changes in the blood and the vessels to determine the mechanism of these disturbances.

Changes in the behavior of blood and in the concentration of its constituents are the result of essential hemorrhagic diseases, while changes in the functional behavior and structural integrity of the blood vessels are the result of nonhemorrhagic diseases. In the former the defect determining the hemorrhagic disease is actually within the blood, reflecting, of course, abnormalities in the reticulo-endothelial system. In the latter the defect is in the vascular wall without any disturbance in the blood.

Whatever the clinical impression of the type of hemorrhagic disturbance, every child requires a complete blood study including the hemoglobin content and the red cell, the white cell and the differential count. This rules out at once the presence of leukemic processes, bone marrow and splenic diseases. Then the determination of the clotting time, the clot retraction time, the bleeding time, the platelet count and the degree of platelet stability all indicate the type of change involved in the blood. If the results of these procedures are normal, it is further necessary to determine the content of the blood-clotting constituents, fibrinogen, prothrombin and antithrombin. Finally the tourniquet test is applied, the capillary nail beds are examined microscopically and the fluid output is measured to determine the presence of vascular dysfunction. No single procedure is ever diagnostic of hemorrhagic disease, for it takes the correlation of all these determinations with the family history, its hemorrhagic tendencies, the child's previous hemorrhagic history, and the present clinical condition to establish the diagnosis.

A NEW CLASSIFICATION OF HEMORRHAGIC STATES

Modern diagnostic procedures correlated with the clinical manifestations of hemorrhagic disturbances necessarily lead to a well defined classification. The

Fig. 3—Analysis of hemorrhagic symptomatology in 5,000 sick children

disease entities that produce changes in blood-clotting substances constitute one group of hemorrhagic diseases, while those that produce changes in the vascular endothelium constitute another group of so-called non-hemorrhagic diseases. Although vascular injury is present in all hemorrhages, it is not the determining factor in the disease process when the blood constituents are actually altered. Every hemorrhagic state involves a controlling factor in the blood or in the vas-

cular endothelium as causative of the disease. In both blood clotting and vascular dysfunctions there are acquired and hereditary diseases. If the prothrombin is deficient in the new-born, hemorrhagic disease results, if the platelets are diminished, thrombocytopenic purpura, if fibrinogen is deficient hemorrhagic diseases of the liver result. If any of these blood clotting constituents are either defective or deficient from infancy, the respective familial diseases appear.

On the other hand if the vascular endothelium suffers from malnutrition, scurvy or marasmus with normal blood pictures in the clotting constituents results. Likewise, if the capillaries are injured by allergens, allergic purpura is the outcome. Again vascular injury may be produced by chronic infections and chemical poisons with resultant hemorrhagic symptoms. And besides these types of vascular injury one may inherit actual defectiveness in the capillary structures and thus suffer from a familial disease. Each of these diseases originating in the blood or in the capillaries is amenable to control to the extent that the deficient or injured

prolonged or even normal, but determination of the clotting constituents reveals a decreased content of prothrombin or fibrinogen content of the blood. The anti-thrombin concentration is usually increased, but the platelets are normal in both quality and quantity. I have observed no evidence that the vascular endothelium is

Fig. 5—Index of blood-clotting function

Fig. 4—Essential diagnostic procedures for hemorrhagic disturbances

factor is replaced or regenerated therapeutically. The control of the essential hemorrhagic disease or the non-hemorrhagic diseases depends on the proper classification of the disturbance. Once the mechanism of the bleeding symptoms is understood, the therapy indicated either supplies deficient blood-clotting constituents or decreases vascular permeability. The chronicity of hemorrhagic disturbances necessitates continuous clinical supervision in the prevention of recurrent hemorrhagic episodes.

DIETARY CONTROL OF CHRONIC HYPOTHROMBINEMIA

A bleeding tendency is not infrequently observed as a persistent manifestation of apparently well children. They are undernourished for their body build and are not derived from hemophilic families. Usually the bleeding symptoms are trivial and are presented only as a complaint incidental to an irrelevant acute illness. Epistaxis and easy bruising are outstanding symptoms although other bleeding disturbances may occur. Physical examination is usually negative and clotting time

at all affected as judged from the tourniquet test and the microscopic examination of the capillary nail beds.

Such benign bleeding manifestations are evidences of nutritional deficiency. The outstanding factor common to all is a syndrome which I shall designate hypothyrombinemia. Both prothrombin and fibrinogen are derived from the liver. Their decrease in these cases is not a result of impaired liver function, but rather the consequence of protein deficiency. Prothrombin is a protein substance which has been observed to increase in the blood following high protein diets. A further consequence is a subsequent diminution of the bleeding symptoms. The associated anemia in these undernourished children is unrelated to the bleeding symptomatology. The anemia observed is a result of nutritional deficiency.

The prevalent notion that hemorrhage follows anemia is unfounded. Bleeding in acute or chronic anemia is not observed even when the hemoglobin is as low as 10 per cent and the red cells drop to one million. Never does hemorrhage occur in severe chlorosis or in any of the anemias unless there is bone marrow injury. Such is not the case in these children with mild recurrent bleeding following trauma. Furthermore, there is no evidence of hemorrhage in the severest hydremias. The blood proteins are reduced to one-third their normal

Fig. 6—Effect of diet on blood clotting function. Clotting diet: proteins, gelatin and fat increase blood clotting constituents. Bleeding diet: fruits, vegetables and carbohydrates decrease blood clotting constituents.

level, which produces no disturbance in the nutrition of the vascular endothelium. The basis for the hemorrhagic tendency in the group of children here presented is a diminished prothrombin or fibrinogen content of the blood corrected within two weeks by the administration of a high protein diet. I have observed a hypo

thrombocytopenia in a group of boys who were referred to me as possible hemophilic patients. Thus has the "clotting diet" become effective in the control of a chronic hemorrhagic condition confused with hereditary hemophilia.

TREATMENT OF CASES OF THROMBOCYTOPENIC PURPURA

Purpura is the most universal of hemorrhagic symptoms. The pictures may characterize a well defined disease entity of the reticulo-endothelial system or be a symptomatic manifestation of bone marrow diseases, splenic diseases, leukemic processes, infectious inva-

of the physical observations that the type of essential purpura may be determined as a basis for effective treatment. The following cases are illustrative of my approach in the control of purpuric disturbances.

(a) *Correcting Nutritional Deficiency*—Dr. Marton's boy developed petechiae over the gums and palate and bled from a loosened tooth at 7 years of age. Recurrent nosebleeds and purpuric spots throughout the body continued over a year. Periodic examination of his blood picture by several physicians confirmed the diagnosis of thrombocytopenic purpura. He came under my observation at the age of 8 when I found his nutritional history most significant. A markedly allergic boy with chronic eczema, he was quantitatively deprived of protein and

sions, chemical injuries or allergic offenses. The essential purpuras resulting from reticulo-endothelial disease are particularly amenable to treatment once the diagnosis has been determined and their mechanism mastered. Essential thrombocytopenic purpura is precipitated abruptly with bleeding from the mucous membranes and into the skin as purpuric eruptions.

The blood shows a marked diminution of the platelets, a leukocytosis, a posthemorrhagic anemia with evidence of erythropoiesis, a normal or slightly delayed clotting time, a prolonged bleeding time, a nonretractile clot and a marked capillary resistance test. While this blood picture is characteristic, the clinical manifestations are variant so far as they have a specific bearing on the purpuric mechanisms. It is in the interpretation

fat. His blood picture showed a hemoglobin of 65 per cent, red blood cells, 3,800,000, white blood cells, 12,000, platelets, 40,000, bleeding time sixteen minutes, clotting time, three minutes. Medical consensus was for splenectomy as a last resort. A high fat and protein diet alone brought the platelets from a further drop of 20,000 to 400,000, with complete disappearance of purpura since 1927.

Typical thrombocytopenic purpura was cleared in this boy by nutritional therapy. The basis for this approach was a careful study of the nutritional history as part of a clinical picture. Dietary fat deficiency correlated with the lipid nature of platelets led to this treatment. I have found high protein and high fat diets in the so-called clotting dietary effective under similar conditions of dietary fat deficiency. One boy

of 4 developed a mild thrombocytopenic purpura, which persisted for six months, when a clotting dietary cleared the condition without further treatment. He was deprived of fat for over two years because of a chronic celiac condition. Another child similarly treated, developed purpura in the course of cyclic vomiting. The replacement of fat in the dietary brought prompt recovery from purpura.

Prolonged nutritional deprivation of the gross constituents in the dietary such as protein and fat does not always produce deficiency disease. Much of the symptomatology resulting from one-sided diets, therapeutic or habitual must be promptly corrected once hemorrhagic manifestations appear. Not infrequently such simple dietary procedures alleviate apparently alarming conditions.

(b) *Eliminating Infectious Foci*—D. T., a girl aged 6 years suddenly developed nosebleeds, hematuria and petechiae over the extremities following a severe infection of the upper respiratory tract. The child was undernourished for her body build, the tonsils were diseased, the spleen was 2 cm below the costal border. Roentgen examination of the sinuses was negative. Examination of the blood revealed hemoglobin 50

Then there were profuse nosebleeds, bloody vomitus, confluent facial hematomas, watery stools and vaginal bleeding. The diagnosis of acute thrombocytopenic purpura was confirmed by several attending physicians. Repeated transfusions aided the child over this severe attack. Purpuric manifestations recurred following short remissions for over a year. Then the child came under my observation. Examination revealed hemoglobin 75 per cent, red blood cells, 4,000,000, white blood cell 12,200, polymorphonuclears were 70 per cent, platelets, 60,000, bleeding time, eighteen minutes, clotting time, three minutes, tourniquet test, positive, clot retraction, deficient. The child showed clinical and roentgenographic evidences of chronic sinusitis. She was promptly immunized against the hemolytic streptococcus obtained from the sinus washings. The child has been free from purpura for over one year.

Infectious etiology in purpura is widespread. It becomes of determining significance in the treatment of purpura. If the infection is self limited, all forms of therapy directed at the symptomatic purpura will be of transient avail until the infectious process has passed. Then residual foci must be eliminated if chronic purpura is to be prevented. But if the infectious invasion is nonapparent in the face of dramatic purpuric bleeding, concentrated effort must be directed for its isolation. Then and only then can specific therapy against that infection halt hemorrhagic occurrences.

I have studied a child who was admitted with precipitate purpura following several months of bleeding from the gums. The blood picture was characteristic of thrombocytopenic purpura with platelets to 40,000. But the purpura did not clear until specific systemic therapy was administered against the causative Vincent's infection. I have seen thrombocytopenic purpura complicating pneumonia in a six months old infant. There were severe hemorrhagic symptoms, marked anemia, a platelet count varying between 60,000 and 90,000 and bleeding time from ten minutes to one hour. The purpuric picture persisted for one month simultaneously with otitis media as a focus despite recovery from the pneumonic process. Repeated transfusions with careful supervision of the offending otitis media eliminated the purpura. I have also observed a course of thrombocytopenic purpura complicating malignant diphtheria, congenital syphilis, miliary tuberculosis and sepsis, respectively. Treatment was necessarily directed at the infectious agents, for the purpura persisted throughout the duration of these infections.

(c) *Regulating Ovarian Function*—T. S., a girl, aged 13 years, suddenly developed purpuric spots over the extremities. The onset of the bleeding symptoms was simultaneous with that of the first menstruation at 12½ years. Then there was not only an excessive loss of blood but bleeding gums and easy bruising as well which recurred with each menstruation. Examination revealed hemoglobin, 65 per cent, red blood cells, 4,000,000, white blood cells 9,200, polymorphonuclears 68 per cent, lymphocytes 20 per cent, platelets 96,000, bleeding time, ten minutes, clotting time, twelve minutes. Treatment with active ovarian extract gradually diminished the recurrence of severe menstrual purpura, so that all hemorrhagic symptoms were finally eliminated by the fifth month.

Ovarian dysfunction not infrequently accounts for the genesis of thrombopenia. Such a relationship is very striking in the clinical cases thus far observed in that purpura recurs with each menstrual cycle. The mechanism of the hormone effect on suppression of bone marrow is unknown. But the diminution of platelets during menstruation, the increased capillary permeability with ovarian deficiency, the preponderance of thrombopenia in females are facts in favor of the administration of ovarian therapy in such cases.

TABLE 3—Treatment of Thrombocytopenic Purpura

- 1 Stimulating platelet formation
 - (a) Nonspecific protein therapy 5 cc intramuscular injection of milk
 - (b) Sterile human serum 2-50 cc intramuscular
 - (c) Whole blood 25-50 cc intramuscular
 - (d) Ovarian hormone 1 cc active preparation intramuscular daily
- 2 Increasing platelet content
 - (a) Blood transfusion effective four days duration of platelets
 - (b) High protein and fat dietary constituents for platelet synthesis
- 3 Decreasing capillary permeability
 - (a) 10% gelatin solution 30 cc orally t i d or 20 cc intramuscularly
 - (b) 10% calcium gluconate 10 cc intravenously (injected slowly) and 10 cc intramuscularly
 - (c) 10% sodium chloride 10-30 cc intravenously (injected slowly)
 - (d) Solution of pituitary effective via vasoconstrictor reaction
- 4 Removing platelet inhibition
 - (a) Elimination infectious foci or specific immunization
 - (b) Splenectomy

Indications: Essential thrombocytopenia, platelet diminution, persistent leukopenia, mild anemia from blood loss, evidences of active hematopoiesis.

Contraindications: Symptomatic thrombocytopenia, platelet diminution associated with deficient production of blood cells, marked reduction of white blood cells and granulocytes, absence and regeneration of hemoglobin and red blood cells.

per cent, red blood cells, 3,400,000, platelets, 55,000. Clot retraction, delayed, tourniquet test, positive, bleeding time, eighteen minutes, clotting time, three minutes. Repeated transfusions and subsequent tonsillectomy cleared the purpura. Although the blood picture became normal and the platelets rose to 200,000, the tourniquet test persisted positive and the child developed black and blue spots following trauma.

Infection not infrequently suppresses bone marrow activity or more usually injures capillary endothelium. This case is illustrative of the destructive effect of the streptococcus toxin on the megakaryocytes as well as of vascular injury. The only obvious related primary focus was the diseased tonsils. Their removal cleared the condition. But the residuum of easy bruising indicates that only part of the infectious focus was eliminated. Once systematic manifestations of an obvious infection appear, there result simultaneous multiple foci, difficult if not impossible to eliminate. One is thus confronted with foci rather than foci of infection to be eliminated in the treatment of purpura. But the early establishment of causative relationship of such foci should lead to their prompt eradication if control of the purpura is the consequence.

Dr. Wonnus Child. A girl aged 10 years, first developed purpuric spots over the left knee only to be followed by profuse crops throughout the entire body on the following day.

(d) *Indications for Splenectomy*—J W, a boy, aged 15 years, suddenly collapsed, bleeding for the first time from the nose, gums and pharynx. Then appeared petechiae over the mucous membranes and crops of purpuric spots over the chest, pelvis and extremities. The physical examination showed nutritional dystrophy, moderate lymphadenitis and an enlarged spleen. The blood picture showed a hemoglobin of 40 per cent, red blood cells 2,500,000, white blood cells 3,200, polymorphonuclears, 24 per cent, lymphocytes, 70 per cent, reticulocytes, 0.2 per cent, platelets, 25,000, clotting time, eight minutes, bleeding time, eighteen minutes, clot retraction, zero, the tourniquet test was positive. Hemorrhage became uncontrollable and transfusions were of little avail. Although the medical diagnosis was aplastic anemia the surgical consensus was for splenectomy. The blood picture revealed a symptomatic cytopenia associated with marked reduction in the white cells and granulocytes as well as with an absence of all signs of regeneration of hemoglobin and the red cells. Besides, there was no evidence of increased destruction of red cells in stained smears, no fragmentation of red cells and the icteric index was low.

Splenectomy is not a specific in the control of hemorrhage. Its effectiveness is limited to essential thrombocytopenic purpura and several other diseases with similar mechanism wherein primary splenic disease affects bone marrow function. This necessarily excludes primary leukemic processes and bone marrow diseases. Even in the limited number of these cases in which splenectomy is indicated, it is as yet not altogether possible to determine preoperatively in which this operation is the procedure of choice. The case cited is illustrative of a condition in which splenectomy should not be performed. Surgical specificity is life saving in emergencies, but misapplied operative intervention interferes with the prognosis and with progress. Splenectomy is contraindicated if the blood picture suggests a deficient production of blood elements other than the platelets. Therapeutic splenectomy is out of the question if the hemoglobin and red cells show more marked reductions than simple hemorrhage would produce, if there is a marked leukopenia, particularly in the granulocytes, and, finally, if in the presence of these reductions in the blood elements there is no evidence of active hematopoiesis. Mere reduction in platelets is never an indication for splenectomy. Every medical effort must be made for a complete correlation of all the blood observations with the clinical picture before yielding to splenectomy.

M T, a girl aged 4 years, showed recurrent purpuric spots over the face and chest for two years. With each crop there was simultaneous bleeding from the gums, nose and throat. A loosened tooth bled continuously for two days, requiring hospitalization. The physical examination was negative and even the spleen was not palpable. Examination revealed hemoglobin 60 per cent, red blood cells 3,000,000, white blood cells, 12,000, platelets, 30,000, bleeding time, fifteen minutes, clotting time, three minutes, clot retraction zero, tourniquet test, positive. Splenectomy was performed following repeated transfusions. All hemorrhages stopped and within twenty-four hours the platelets rose to 200,000. One week after the operation the platelets were 350,000, the second week 500,000, the third week, 700,000, and the blood picture became normal.

Such is the intermittent course common to chronic thrombocytopenic purpura. Remissions may last a few weeks or continue for months or even years with the platelets at low levels. When they fluctuate about the danger zone bleeding is imminent. With the purpuric process continuous the blood picture is abnormal even though the clinical manifestations are not always apparent. When bleeding does occur, the blood picture frequently shows a relative lymphocytosis which may be confused with lymphatic leukemia. A preponderance

of polymorphonuclears in purpura is indeed the more favorable index of bone marrow activity.

Treatment is directed at methods of raising the platelet content of the blood. Transfusions arrest bleeding not only because they contribute tremendous numbers of platelets but particularly because they stimulate bone marrow activity. Mere addition of platelets is transient because of their four day duration. Caution must be exercised in the transfusion of purpuric children because of their great susceptibility to shock of an already injured reticulo-endothelial mechanism. Therefore, accurate typing and matching must not be foregone, even in emergency transfusion. Under such circumstances it is preferable to tide the patient over with intramuscular blood in the interim of selecting a suitable donor. Even nonspecific protein therapy is effective in the early stages of the disease in that it induces marked rises in platelets and decreases capillary permeability.

But platelet reduction in purpura is not altogether responsible for bleeding. I have seen extreme thrombopenia without hemorrhage as well as the converse condition, indicating effect on the capillary walls as well as on the platelet mechanism. Therefore it is

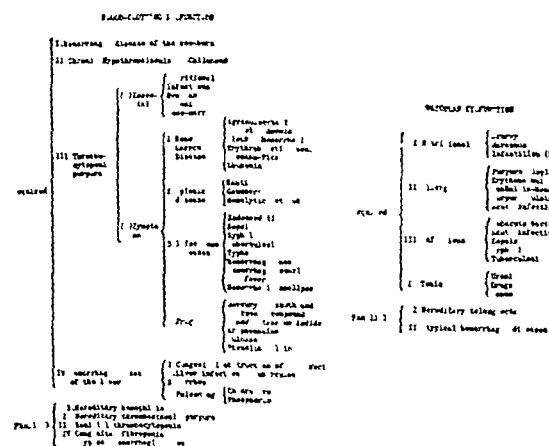

Fig 7—Hemorrhagic diseases in infancy and childhood

necessary in the treatment of purpuric bleeding not only to increase the platelet level of the blood but to decrease the capillary permeability as well. This may be accomplished by the intravenous administration of from 10 to 25 cc of 10 per cent calcium gluconate. This procedure may be reinforced by the oral administration of calcium salts. Local bleeding from mucous membranes may be arrested by applying dressings of a proprietary synthetic vasoconstrictor, a stable intermediate of epinephrine. Thromboplastic agents are quite ineffective locally and systemically.

But the chronicity of essential purpura may be cured by splenectomy. It is safe when properly timed and effective when indications are clear cut. Chronic cases may show a persistent mild leukopenia, indicating some exhaustion of the bone marrow as well as anemia resulting from the loss of blood. Both of these conditions are indications for splenectomy, provided there is evidence of active hematopoiesis. If bleeding is controlled by medical measures and there is a persistent leukocytosis the bone marrow is reacting and so it is preferable to continue to control the problem without splenectomy. In acute purpura, splenectomy may be a life-saving measure provided preliminary large transfusions are given daily to bring the hemoglobin and the

red blood cells to a favorable level. In such acute emergencies the platelet level is of no factor in surgical prognosis. Splenectomy is the procedure of choice when transfusions fail to arrest bleeding in a child that is afebrile, whose blood shows active regeneration and whose general condition after transfusion indicates fair surgical risk. Purpuric bleeding is promptly arrested after ligation of the splenic vein and no bleeding continues during or after splenectomy. But every child who leaves the operating room in good condition requires continuous medical supervision. Not infrequently, shock suddenly follows splenectomy. It may be immediate or delayed, hence a donor should be on hand for an emergency transfusion to combat post-operative collapse.

Clinical cure is not always complete following splenectomy. The more careful the blood picture conforms to the characteristics of the essential type of thrombocytopenic purpura the better the end result. The spleen in this type of purpura inhibits the production of platelets by the bone marrow. More specifically deranged splenic function is the result of defective separation of the platelets from normal megakaryocytes. Therefore, removal of the spleen produces a rapid and persistent rise of platelets to levels beyond the normal range for years following operation. But in the type of thrombocytopenic purpura in which there is a deficient production of megakaryocytes by the bone marrow the removal of the spleen is less beneficial if not unnecessary. It is this type of purpura that is difficult if not impossible to differentiate preoperatively unless the blood picture reveals semblances of aplastic anemia. Postoperatively there is a transient rise in platelets with an apparent clinical cure, but subsequently they fall again to low levels when hemorrhages recur. The return of purpuric symptoms has also been attributed to residual accessory spleens, fairly common in children. Their presence following splenectomy thus furnishes a source of inhibition of platelet production. Therefore there is dual responsibility medically to differentiate the type of essential purpura that will respond to splenectomy and surgically to the removal of all splenic tissue.

EVALUATING SYMPTOMATIC THROMBOCYTOPENIC PURPURA

Purpuric symptoms associated with diminished blood platelets occur in the course of many diseases. Exceptionally do they characterize the essential form of purpura. They are consequences of acute infectious diseases, of sepsis, of chemical injury, of primary blood diseases and of conditions in which the bone marrow is replaced by other tissues, as in Gaucher's disease, Niemann-Pick disease, osteosclerosis, marble bones and a variety of milder toxic disturbances characterized by a reduction in the circulatory myeloid elements of the blood such as agranulocytosis, aplastic anemia and aleukia haemorrhagica. The thrombocytopenic purpura therefore represents but one of several destructive processes in the parenchyma of the bone marrow. The injury of the megakaryocytes diminishes platelet formation just as injury to other parts of the bone marrow produces comparable changes in the blood cells. Obviously, this specific treatment in the selective injury to the megakaryocytes does not apply to more extensive injury to the bone marrow. The treatment of symptomatic thrombocytopenic purpura depends wholly on the nature of the primary disease.

(To be continued)

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

OHIO INFANT RESUSCITATOR ACCEPTABLE

The Ohio Chemical and Manufacturing Company manufactures and offers for sale to the profession an Infant Resuscitating Outfit which comprises a cylinder with foot ring yoke valve wrench, rubber bag, rubber tubing, hose clamp and baby face inhaler. It is recommended for use with a mixture of 5 per cent carbon dioxide and 95 per cent oxygen.

The Council investigated this device and the report follows. The above mentioned machine for the resuscitation of the newly born infant was employed in eleven cases of newly born infants afflicted with asphyxia of various degrees at the time of birth.

The development of these babies varied. Two were somewhat premature weighing 2,760 and 2,950 Gm., respectively and the calculated menstrual age was 38 weeks. Six were at term and three showed some evidence of postmaturity as evidenced by their weight and calculated menstrual age.

Evidence of fetal distress prior to delivery was not present in all cases. In one case there was evidence of a Brandt's contraction ring. In five cases there was no evidence of cord compression or fetal distress prior to birth. In two of the remaining five cases, meconium appeared in the amniotic fluid. In one of these, meconium was present for three and one half hours prior to delivery. In neither one of these cases did the fetal heart go below 100 per minute. In three cases the heart tones varied enough to cause some apprehension and in one case disappeared altogether for a minute or two, prior to a low forceps delivery.

Medication During Labor—In four of the five cases just mentioned, morphine was administered, with or without scopolamine. Only two patients in the entire series did not have morphine alone, or combined with some other sedative. Both of these cases were breech presentations and offered difficulties during delivery. There was some aspiration of mucus and fluid in both cases. No patient received more than one dose of morphine during labor. The time of administration of the morphine varied from one hour to fourteen hours prior to delivery. Scopolamine was used in conjunction with morphine three times, and magnesium sulphate was administered once.

Anesthetics Used—Rather deep ether narcosis was used during the first stage of labor in one case. Ethylene and oxygen anesthesia was used in all cases and twice in combination with ether.

Length of Labor—The length of labor in most of these cases was relatively short, the average being twelve hours and twenty minutes. There was one case in which labor was prolonged to thirty hours.

The Presentation and Delivery—There is a high percentage incidence of breech presentations, there being three breech extractions, three spontaneous deliveries, three low forceps operations, one midforceps and one Porro cesarean section. There was some disproportion due to contracted pelvis in three cases.

Degree of Asphyxia—Eight of eleven babies were asphyxiated the degree varying considerably. Two showed signs of asphyxia pallida. In six there was a syndrome of asphyxia livida. One baby was apneic. No apnea or asphyxia of notable degree was present in two cases. In two cases the degree of asphyxia was so profound as to cause apprehension.

Ohio Infant Resuscitator

Etiology of Asphyxia—The following factors were thought to be responsible for the causation of the asphyxial birth trauma, sedatives and analgesics, ether and anesthesia, cord compression and respiration. Frequently more than one of these factors were present in individual cases. The morphine was undoubtedly responsible for the apnea in several cases, and one case of pronounced asphyxial lividity was ascribed to this agent.

Aspiration in small amounts occurred twice, and of larger amounts in two cases. This presented some mechanical difficulty to the establishment of normal respiration. Three babies seemed to have been definitely affected by injury, and there were two cases with definite cord compression, one in a difficult breech delivery in which the legs were astride the cord, and another in which the cord was caught over a shoulder and drawn sufficiently tight to cause blanching of the vessels. The case with the Brandt's contraction ring previously mentioned, resulted in the birth of the baby that responded poorly to the initial gas therapy.

The Heart and Circulation—The fetal circulation was impaired in all but two cases at the time of birth. The heart rate was reported to be slow in three cases. It was recorded at 60 per minute in two instances, 70 in two, 90 in one and 100 in one. The quality of the heart tone was usually strong.

Character of Respirations Before Treatment—Eight babies were not breathing as the treatment was instituted. In two cases the baby was gasping irregularly, and in one the respirations were already established. Some degree of artificial respiration was usually necessary to introduce the gas into the lungs. The tracheal catheter was used in nine cases for the aspiration of fluid and mucus. In two of these cases it was used for insufflation.

Pharyngeal Reflex—The pharyngeal reflex, which has been found to be a reliable index for the degree of asphyxia and a good prognostic sign, was normal in three infants, all of which responded readily to gas therapy. In five cases the reflex was feeble and the reaction of the infant was delayed. Two of the three babies without pharyngeal reflex were difficult to resuscitate, one requiring over twenty minutes before the establishment of normal respiration.

Percentage of Gas Used—In six of the milder cases, the mixture of gases was 95 per cent oxygen and 5 per cent carbon dioxide. The effect of this mixture is identical with that of oxygen. It is usually all that a mildly or moderately asphyxiated infant requires. In two babies 90 per cent oxygen and 10 per cent carbon dioxide was used, and in three cases the percentage was 70 and 30, respectively.

Time Intervals—The average interval between birth and the institution of treatment for the asphyxia was 47 minutes, the shortest interval being one minute and the longest twelve minutes. The gas was administered to one apneic baby with cyanosis for twenty minutes after birth, with ultimate excellent results. Three babies were breathing but were not in satisfactory condition prior to administration of the gas. Of the remaining eight, the average interval between the application of gas and the onset of respiration was 275 minutes, the shortest being one minute and the longest ten minutes.

All of the babies, except one, were in good condition when they left the birth room. Subsequently, no later treatment was required in the nursery in any case. There were no fatalities in this series, so no autopsy data are available regarding the condition of the lungs or air passages. Two babies had contracted pupils due probably to morphine and one infant had a slight stridor and whining cry, suggestive of birth trauma. All babies left the hospital in the usual time in good condition.

The case with complete asphyxia lasting twenty-two minutes, is worthy of special mention. This baby was a breech presentation in a primipara, aged 41. The mother had received ether anesthesia once prior to the administration of ethylene and ether. At the time of the Porro cesarean section two doses of morphine had also been administered. The fetal heart was very slow—about 40 per minute. In this case the gas mixture of 70 per cent oxygen and 30 per cent carbon dioxide was used. Heat and artificial respiration were needed for some time before the mixture could be introduced into the lungs.

The merits of this machine seem to be its efficiency and practicability, which can be secured at a relatively small initial

expenditure. The apparatus is compact and is not cumbersome. It is durable and light and seems to meet all requirements except for the disadvantage arising from the necessity of changing tanks in order to vary the percentages of the gases given. The tanks, however, if available, can be changed within a very short time. The safety cock, designed to prevent the forcing of too much gas under too great pressure into the fetal air passages, seemed to operate consistently and effectively. In all of these machines designed for resuscitation of newly born infants, care must be taken to clean the mouthpiece and tube prior to insertion in the mouth and nasopharynx.

The Council declares the Ohio Infant Resuscitator eligible for inclusion in the list of acceptable devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH, Secretary

PRO-TEK NOT ACCEPTABLE FOR N N R

Pro-Tek is the proprietary name under which the DeVilbiss Company markets "a protective skin film" for workers' hands, also recommended for use on the face. The product is stated to be composed of soap (Ivory Soap Flakes), "free caustic," moisture sodium silicate, and glycerin. While no quantitative statement of composition appeared on the labels or in the advertising submitted to the Council, the firm expressed the intention of including such a statement if the product should be found otherwise acceptable by the Council. In accordance with the recently adopted Council ruling, a quantitative statement of composition should appear on the label and in the advertising. The DeVilbiss Company furnished a report from Dr. Arthur P. R. James, a reputable dermatologist of Toledo, Ohio, stating that Pro-Tek is nonirritating and harmless. The firm also furnished sworn statements (all signed by Dr. James) from several workers in naphtha, benzene, coal tar products, alcohol derivatives and ordinary lacquer thinners, all of whom testified to having used Pro-Tek and of having had no ill effects from the substances with which they work, as the result, in their opinion, of the use of Pro-Tek. The DeVilbiss Company submitted an advertising circular to be distributed to the public entitled "Pro-Tek The Invisible Glove", also a whole catalogue sheet captioned "Pro-Tek The Protective Skin Film."

If this were entirely a nonmedical article for instance, if it were to be used solely as a cleansing agent or to protect the hands against soiling, the name "Pro-Tek" would appear to be permissible under the Council's rules. However, the preparation is also to be used as a protection to the skin against irritation, and through this it becomes a medicinal agent that, to be made acceptable, must comply with the Council's rules for medicinal articles. Its action is not strictly mechanical but rather physical, like that of other demulcents and emollients, including protective ointments, pastes, glycerin and skin mucilages.

The Council held that, while the product might be entitled to a coined name, this name must not (as does the name "Pro-Tek") suggest therapeutic properties and, further, that such a name should indicate the potent constituents of the mixture. The Council held that the soap, the silicate and the glycerin all play a part in the action of the product but that the presence of the silicate is probably the most important. The Council suggested to the manufacturer that a name such as "Siliso Cream" would be acceptable.

When the firm was informed of the Council's decision with reference to this product it replied that conditions were such as to make it impossible to give up the name "Pro-Tek" or to accept the change in name suggested by the Council. The Council was therefore obliged to declare the product submitted as "Pro-Tek" unacceptable for New and Nonofficial Remedies because it is marketed under a therapeutically suggestive proprietary name and also without a declaration of the constituents on the label or in the advertising.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULE AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

RAYMOND HELFICG Secretary

BEECH-NUT STRAINED BEETS

(SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved beets retaining in high degree the nutritive and mineral values, slightly seasoned with salt.

Manufacture—Dark red beets are thoroughly washed, cooked in their own steam for one hour with a small amount of added water and blanched, and salt (0.5 per cent) is added. The beets are strained, processed and packed as described for Beech-Nut Strained Carrots (THE JOURNAL, Nov. 11, 1933, p. 1562).

Analysis (submitted by manufacturer) —

Moisture	91.3
Total solids	8.7
Ash	1.5
Sodium chloride	0.5
Fat (ether extract)	0.0
Protein (N × 6.25)	1.2
Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	5.4

Calories—0.3 per gram, 9 per ounce.

Standards and Claims of Manufacturer—See these sections for Beech-Nut Strained Carrots (THE JOURNAL, Nov. 11, 1933, page 1562).

SUNRISE PANCAKE WHEAT FLOUR

Manufacturer—The Concordia Milling Company, Concordia, Kan.

Description—Pancake flour mix prepared from patent hard wheat flour, whole wheat flour, dextrose, calcium acid phosphate, baking soda and salt.

Manufacture—The ingredients are mixed in definite proportions and packed in bags.

Analysis (submitted by manufacturer) —

Moisture	12.9
Ash	1.4
Fat (ether extraction method)	1.4
Protein (N × 5.7)	9.9
Reducing sugars as invert	1.0
Sucrose (copper reduction method)	1.1
Crude fiber	0.7
Carbohydrates other than crude fiber (by difference)	70.7

Calories—3.4 per gram, 97 per ounce.

WARDS MILK MAID BREAD

Manufacturer—The Ward Baking Company, New York.

Description—A milk bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p. 817) prepared from flour, water, skim milk powder, sugar, butter, salt, yeast, malt syrup and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer) —

Moisture	38.0
Ash	1.7
Fat (Ward Laboratory method)	2.1
Protein (N × 6.2)	8.4
Crude fiber	0.1
Carbohydrates other than crude fiber (by difference)	49.7

Calories—2.5 per gram, 71 per ounce.

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for mill bread.

KARO POWDERED

Manufacturer—Corn Products Refining Company, New York.

Description—Spray dried corn syrup containing essentially dextrins, maltose and dextrose.

Manufacture—Corn syrup prepared by the hydrolysis of corn starch with dilute hydrochloric acid (see 'Karo [Crystal White]' in THE JOURNAL, Jan. 9, 1932, p. 143) is concentrated to a density of 1.36 (20°C./20°C.) spray dried and automatically and hygienically packed in enameled tins under air controlled conditions.

Analysis (submitted by manufacturer) —

Mixture	per cent
Ash	2-5
Fat (ether extract)	0.3
Protein	0.1
Dextrins (nonfermentable carbohydrates)	0.0
Maltose (fermentable sugar minus dextrose)	53-55
Dextrose (Steinhardt's method of Spiritusindustrie 56)	26-27
64-65 (No. 12) 1933)	16-17
Free from starch	

No protein reaction is obtained with (1) acetic acid and potassium ferrocyanide, (2) saturated sodium chloride and acetic acid, (3) trimetaphenol (picric acid) or (4) nitric acid and magnesium sulphate.

Calories—19 per gram, 110 per ounce.

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a palatable carbohydrate for the nutrition of invalids and convalescents. Protein free and hence nonallergic.

SANITA BRAND STERILIZED UNSWEETENED EVAPORATED MILK

Distributor—The Ranner-Davis Mercantile Company, Arkansas City, Wichita, Anthony, Kan., Enid, Ponca City, Woodward, Okla.

Packer—The Page Milk Company, Merrill, Wis.

Description—Canned, unsweetened evaporated milk, the same as the accepted Page Evaporated Milk, Sterilized Unsweetened (THE JOURNAL, May 30, 1931, p. 1872).

MCCAHAN'S SUNNY CANE SUGAR

(a) LATPA FINE GRANULATED

(b) POWDERED

(c) CONFECTIONERS XXXX

(d) CONFECTIONERS XXXX WITH 3 PER CENT

CORNSTARCH TO PREVENT CAKING

(e) HOSTLESS TABLETS

(f) PARTY CUBES

Manufacturer—The W. J. McCahan Sugar Refining and Molasses Co., Philadelphia.

Description—(a) Finely granular refined cane sugar, (b, c, d) Powdered refined cane sugar, (d) contains 3 per cent corn starch to prevent caking, (e, f) Refined cane sugar in loaf or cube form.

Manufacture—(a) Imported unrefined cane sugar is passed through a crusher to break up any lumps that exist and is then mixed with a thin syrup to loosen the molasses surrounding the crystals, centrifugated and washed with cold water while rotating. (The syrup removed is used in the manufacture of Old Time Brown and Golden Yellow sugars.) The washed sugar is dissolved in water, the dark brown solution is treated with purifying agents—phosphoric acid and lime—to coagulate insoluble impurities which are filtered out. The clear brown filtrate is passed through a tank of bone black to remove soluble impurities, producing a water clear sugar syrup which is concentrated in vacuum at low temperature until a magma (a concentrated mass of crystals suspended in syrup) is formed. The magma is cooled and centrifugated, the white crystals are washed free of all trace of syrup, dried with warm air, screened for grading the crystals and packed automatically as 'granulated sugar'. (b, c, d) Refined cane sugar prepared as described under (a) is reduced to a fine powder and packed in cartons. In the

case of *d*, the powdered sugar is admixed with corn starch to the extent of approximately 3 per cent of the mix, and automatically packed

(*c, f*) Refined cane sugar, prepared as described under *a*, is moistened with a concentrated sugar syrup. The moist crystals are molded into desired forms which are dried with hot air, cooled, and packed in cartons

Claims of Manufacturer—Highly refined cane sugars for manufacturing, cooking and table use

MOFFAT COOKING CHOCOLATE UNSWEETENED

Manufacturer—Moffat, Inc., Boston

Description—Ground cacao nibs or "chocolate liquor" in cake form

Manufacture—Different varieties of cacao beans are separately cleaned, roasted cracked while hot, fanned to remove the cacao shell, stored in separate open hoppers and blended in formula proportions. The blend is finely ground, the resulting chocolate liquor is molded into one ounce cakes, which are cooled automatically wrapped in wax paper, and packed in cellophane-wrapped cartons

GILSTER'S FEATHERLITE CAKE FLOUR (BLEACHED)

Manufacturer—Gilster Milling Company, Chester, Ill

Description—Soft winter wheat short patent flour, bleached. The same as Gilster's Best Flour (Bleached) (THE JOURNAL Nov 4, 1933, p 1483) excepting that it is more finely bolted

BOWMAN'S WHOLE MILK HOME LEADER BRFD (REDI-SLICED AND PLAIN)

Manufacturer—A Bowman & Son, Roanoke, Va

Description—A milk bread made by the sponge dough method (method described in THE JOURNAL March 5, 1932, p 817) sliced and unsliced. Prepared from patent flour, water, powdered whole milk shortening sucrose, salt yeast, and a yeast food containing calcium sulphate, ammonium chloride sodium chloride and potassium bromate

HUBINGER GOLDEN TABLE SYRUP

(CORN SYRUP AND REFINERS SYRUP)

Manufacturer—The Hubinger Company Keokuk, Iowa

Description—Table syrup, corn syrup flavored with refiners syrup

Manufacture—Corn syrup prepared by the usual method of acid hydrolysis of corn starch (see Pemick Golden Syrup, THE JOURNAL April 2 1932 p 1159) is blended with high grade refiners syrup. The mixture is heated to 79 C and automatically packed in cans at 76 C

Calories—29 per gram 82 per ounce

Claims of Manufacturer—For cooking, baking and table use or as a carbohydrate supplement for milk modification for infant feeding

IRRADIATED VITAMIN D PASTEURIZED MILK

Distributor—Luick Dairy Company Milwaukee

Description—Bottled pasteurized vitamin D milk irradiated by Steenbock process (patent No 1680,818)

Preparation—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation, see THE JOURNAL Oct 7, 1933, page 1155

Vitamin—Clinical investigation shows this milk to be a reliable antirachitic agent. Contains 50 Steenbock vitamin D units per quart

Claims of Manufacturer—Irradiated antirachitic pasteurized milk having otherwise the natural flavor and food values of usual pasteurized milk

CELLU MAYONNAISE SALAD DRESSING

Manufacturer—The Chicago Dietetic Supply House, Inc., Chicago

Description—Mayonnaise prepared from soy bean oil, fresh eggs, cider vinegar and sodium chloride

Manufacture—Fresh whole eggs and the soy bean oil are beaten to a thick emulsion. Vinegar and salt are worked in and the resulting mayonnaise is packed in glass jars. Small quantities are made at a time, so that fresh products only will be distributed

Analysis (submitted by manufacturer) —

	per cent

THE ORIGIN OF CANCER

Of the many attempts to explain the origin of malignant growths, the theory of a specific parasitic cause has been definitely dismissed by practically all students of the subject. The so-called Cohnheim hypothesis, which would ascribe tumor growth in general to anomalies of embryonic development, does not coordinate with the rather extensive available knowledge of the artificially induced irritational tumors, and Virchow's irritation theory is open to the objection that causative irritation is demonstrable only in a limited portion of cancer cases. Fischer-Wasels¹, who is active in the modern investigation of cancer, has elaborated a theory that seems to reconcile the Cohnheim and Virchow theories, moreover, he has presented significant experimental evidence in support of his views.

A cancer cell represents a biologic variant with entirely new properties, which are transmitted to its offspring. Such cellular mutants, according to the view of Fischer-Wasels, can originate normally only during the developing and differentiating stages of tissue growth. To the extent that cancer occurs in the absence of chronic regeneration, it does so in foci established during the early stages of development, essentially in agreement with Cohnheim's hypothesis. But abnormally there may occur in later life developmental changes that also permit such cellular mutation, for example, when from irritational causes rapid and continued tissue growth is present. Obviously, regenerating tissues resemble in many respects the rapidly growing tissues of the embryo. In these, Fischer-Wasels sees the possibility of origin of what may be called acquired foci of cancerous growth. This view has support in the character of morphologic changes occasionally seen in regenerating tissues, particularly in regenerating epithelium. Here there is not infrequently seen, in circumstances of stimulated growth, a metaplasia from glandular to squamous type—one that is definitely recognized as a frequent precursor of cancer.

¹ Fischer-Wasels, Bernhard. Experimentelle Grundlagen und Folgen der Regenerationstheorie der Geschwulstbildung. Klin. Wchnschr. 11, 1937 (Nov. 19); 1977 (Nov. 26); 1932. Erblichkeit und Geschwulstbildung. Deutsche med. Wchnschr. 59, 1489 (Sept. 29) 1933.

This multiple origin of foci of potential cancer is, however, only half of the complete picture drawn by Fischer-Wasels. It has long been recognized that it is possible artificially to enhance susceptibility to cancer, most typically by the continued administration of arsenic and perhaps less definitely, of indole. Cancer thus developed shows no regional relationship to the site of administration, for instance, in arsenic cancers developing after the treatment of psoriasis by long continued administration of solution of potassium arsenite by mouth the lesions ordinarily are primarily palmar or plantar, at times, multiple primary skin cancers may occur. Similar relations have been suspected with coal tar, but here the general action is ordinarily masked by its striking local effects. However, Fischer-Wasels, as well as a number of other experimenters, has observed the development of skin cancers in tarred animals in sites which protected as completely as possible from the direct action of the tar. have been injured in other ways, as by burning. Further, the greatly increased frequency of lung tumors in tarred animals may well be explained by increase of constitutional susceptibility.

The relation of malignant disease to heredity becomes particularly interesting in the terms of this hypothesis. One evident manner in which heredity could predispose to cancer would be through an inheritable tendency to embryonic maldevelopment of the type causing pre-malignant foci. Constitutional predisposition might, in all probability constitute another inheritable factor, so that malignant tumors might originate on a purely hereditary basis, both essential factors being of that character, or through the inheritance of a potentially cancerous focus with constitutional susceptibility acquired in later life, or through an acquired focus in an individual with either hereditary or acquired susceptibility.

As to the nature of this susceptibility, Fischer-Wasels points out that there is no morphologic alteration that can be recognized in this connection, so that it is apparently of metabolic character. Studies of tissue metabolism in normal animals and in such as are spontaneously cancerous as well as in animals rendered susceptible to cancer by chronic intoxication with tar or arsenic, made in his laboratory, show in the latter two classes a rather general alteration of metabolism from the normal oxidative type to that of the fermentative glycolysis which Warburg has shown to be linked with malignant growth. At present, efforts are being made with some prospect of success to identify associated blood changes more readily recognized.

To his theory as outlined here, Fischer-Wasels has added a number of corollary postulates. Most of these would appear to be of unquestionable validity: the necessity for periods of latent susceptibility and latent cancer development; the necessity, in the so-called irritational cancers, of a variable but usually prolonged period of stimulated and destroyed new growth of tissue, the formation of a potentially cancerous focus

in the course of these regenerative changes. In connection with the last postulate Fischer-Wasels regards as quite impossible one factor which is still open to question—that of the possible transfer of the properties of malignancy to adjacent and primarily uninvolved tissues. Such transfer would appear to occur with the Rous fowl tumors and has apparently been observed in a number of mammalian tumors as well as possibly in carcinoma sarcomatodes. But even should this transfer be established as actual it does not constitute an insuperable barrier to the validity of the hypothesis.

To be thoroughly acceptable a theory should not only serve as an explanation of facts already known but also to map routes into new fields of knowledge. To the extent that the theory here under discussion has been so used by Fischer-Wasels and his co-workers, it has met this demand. Scharlach R, for instance, has long been known to cause local, but delimited, epithelial hypertrophy in sites of injection. Using this to produce local regenerative changes, and the previous and continued administration of arsenic to produce constitutional susceptibility, they obtained hypertrophy which was no longer delimited but clearly cancerous. More recently, the continued administration of indole to mice has been found to cause in them marked lesions of the hematopoietic tissues ranging in character from typical leukemia to lymphosarcoma—an association of results that would seem to support those who have regarded the former disease as a special type of malignancy.²

Whether or not it gives an accurate presentation of the phenomena underlying tumor genesis the theory offers a working explanation of most of the facts of cancer development as they are known at present. That it promises to be productive of an increase of such knowledge is already indicated by its use in suggesting new methods of attack on what is probably the most obscure problem confronting modern medicine.

THE SOCIAL ORDER AND HUMAN HEALTH

The profound industrial and economic depression through which the nation has been passing in recent years has served to awaken many inquiries regarding the future of civilization. There can be no doubt that the so-called century of progress has brought many satisfactions and comforts into human life. The ingenious developments of machinery, the far-reaching promotion of methods of transportation, the successful organization of the functions of production and distribution, the improvement of the agencies and devices that are involved in the supply of food, clothing and shelter, the integration of political and social interests—such procedures provided by the past few generations are responsible for much that has brought relief from “the grind of monotonous all-absorbing toil from which most of our progenitors could not escape. One

could also present an intriguing story of a changed world in which man has in large measure been emancipated from certain degrading conditions that go hand in hand with ignorance and superstition. The eminent American physicist R. A. Millikan has stated

Do you realize that within the lifetime of men now living within a hundred years, or 130 years at the most, all the external conditions under which man lives his life on this earth have been more completely revolutionized than during all the ages of recorded history which preceded? My great-grandfather lived essentially the same kind of life, so far as external conditions were concerned, as did his Assyrian prototype 6000 years ago. He went as far as his own legs or the legs of his horse could carry him. He dug his ditch, he mowed his hay, he did all the operations of his industrial life with the power of his own two arms or the power of his wife's two arms with an occasional lift from his horse or his ox. He carried a dried potato in his pocket to keep off rheumatism, and he worshipped his God in almost the same superstitious way. It was only in the beginning of the nineteenth century that the great discovery of the ages began to be borne in upon the consciousness of mankind through the work of a few patient, indefatigable men.

Meanwhile another side of the story has been developing rapidly in recent months. The men who invented labor-saving machinery, the scientists who developed improved varieties and cultural methods, would have been bitterly disappointed had they seen how our social order was to make a mockery of their handiwork. In an address at Boston before the American Association for the Advancement of Science Hon. Henry A. Wallace,¹ the Secretary of Agriculture, vigorously criticized the assumed perfection of modern progress. He pointed out that during recent times science has been creating another world and another civilization that simply must be motivated by some conscious social purpose if civilization is to endure. Science and engineering, Wallace asserts, will destroy themselves and the civilization of which they are a part unless there is built up a consciousness that is as real and definite in meeting social problems as the engineer displays when he builds his bridge.

Every one is likely to be familiar by this time with the vigorous attacks that are today being developed against the current order. They imply that technological achievement such as has been created is at length likely to be a menace to human happiness unless there is a new order of planning. Secretary Wallace is somewhat specific in his appeal.

We wish a wider and better controlled use of engineering and science to the end that man may have a much higher percentage of his energy left over to enjoy the things which are nonmaterial and noneconomic, and I would include in this not only music, painting, literature and sport for sport's sake, but I would particularly include the idle curiosity of the scientist himself. Even the most enthusiastic engineers and scientists should be heartily desirous of bending their talents to serve these higher human ends.

Are there not additional personal advantages that would accrue to man through the development of new objectives in our social and economic life? Medicine

² Bungele, Walter. Die experimentelle Erzeugung von Leukämie, Myelosen, Lymphadenosen und Lymphosarkom. *Klin. Wchnschr.* 11: 1982 (Nov. 26) 1932.

¹ Wallace, H. A. The Social Advantages and Disadvantages of the Engineering Scientific Approach to Civilization. *Science* 79: 1 (Jan. 2) 1934.

points with pride to its achievements in the century of progress.² True, modern medicine makes no promise of immortality or even rejuvenation, but does it really "offer the living of most lives to the maximum period of expectancy, and such living with health and usefulness"? It is becoming commonplace to speak of the "diseases of modern life"—the morbidity that finds its explanation in large measure in the complex, insistent demands made on the living organism by the exigencies of present-day "civilization." Of what ultimate benefit are the betterment of child life, the conquest of infectious diseases, the superb development of surgery, the refinements of diagnosis, the advances in therapy, the perfection of nursing—how do these great contributions of medical effort profit our nation if its benefactors are in all too early season to become the victims of insidious maladies attributable to the stress of the strenuous life of today? Just as economists complain of the menacing dangers of an unmanaged progress, the hygienist may point to the man-made burdens of human misery due to "advancing civilization." The heart and circulatory disturbances that follow in the wake of our "hustle and bustle", the mental disturbances and maladjustments prompted by modern living and working conditions, the faltering eye and ear, call for a revision of our daily schedules. The "tired business man" and the "tired business woman" of today have upset the equilibrium that nature has intended to prevail among the various powers and activities of the body, and between man and the outside world. Perhaps the new objectives of a saner social order may save man from devastation by his ruthless program of progress.

PLEO-ANTIGENIC BACTERIA

Conclusive evidence that pathogenic bacteria often "dissociate" into two or more variants on routine culture mediums, and that similar "transformations" may occur on the injection of routine laboratory cultures into laboratory animals or during the course of natural clinical infections, has introduced elements of uncertainty into conventional views of the etiology of specific infectious diseases. The alleged diphasic nature of *Bacillus tuberculosis*,¹ for example, and the well confirmed tertiary variant of *Spirochaeta pallida*,² are prophetic examples of complex problems with which future clinicians may be forced to deal. From a practical point of view, the most important changes in pathogenic micro-organisms are not changes in morphology or increases or decreases in specific virulence but conceivable changes in their physiologic functions or specific chemical composition. If, for example, the test tube variant and the primary, secondary and tertiary

infectious phases of the tubercle bacillus are not only quantitatively but also qualitatively different in such characters, it is conceivable that allergies, immunities or specific antibodies may develop during the course of clinical tuberculosis that are beyond the range of detection by current immunologic technics.

Few detailed studies of the possible antigenic or chemical phases of bacterial cells have yet been attempted. Mackenzie and Fitzgerald³ have produced test tube variants of well known paratyphoid and paratyphoid strains by growing the parent cultures in the presence of dilute immune serum or dilute chemical antiseptics. From two to four distinct variants were produced with each of the parent strains, certain ones of which have shown no signs of reversion to their original characteristics after three years of subculture on routine culture mediums. Three familiar colony types were noted among the variants: typical "smooth" colonies of textbook bacteriology, "rough" colonies of current pleomorphic nomenclature, and extremely rough colonies of the "medusa" type. Intermediary stages also were noted. No invariable "linkage" or parallelism was noted between colony type and other microbial characters. "Rough" colonies might be produced by bacteria with otherwise unaltered characters, or marked departures from "typical" morphology or physiologic properties might be demonstrated in bacteria isolated from typical "smooth" colonies.

Antigenic assays were made by testing the power of each variant to stimulate the production of specific agglutinins in rabbits, and by studying reciprocal absorption and cross-agglutination with the resulting antisera. Certain of the artificial variants were found typical in their specific antigenicity, when studied by these technics. Other extreme variants would stimulate the production of no demonstrable specific agglutinins in rabbits, were wholly magglutinable with original type antisera, and were wholly nonabsorptive of original type specific agglutinins. Here also all conceivable intermediary stages were demonstrable.

About ten years ago, Furth⁴ of the hygienic institute at the University of Prague reported data suggesting that such antigenic variations in *Bacillus paratyphosus* are not necessarily merely quantitative in nature. He believed that certain of his laboratory variants had actually gained antigenic components not present in the original parent culture. Mackenzie and Fitzgerald were able to demonstrate the presence of such an acquired antigenic factor in certain of their variants. Furth also described the phenomenon of "convergence" between certain of his bacterial strains, two apparently distinct types or species giving rise to antigenically identical "dissociates." This also the New York investigators were able to confirm.

⁴ Furth, J. *Ztschr. f. Immunitätsforsch.* 35: 133 1923.

There is rapidly increasing evidence that similar antigenic "mutations" can and often do occur during the course of certain natural infections or may be produced artificially by the inoculation of freshly isolated human strains into lower animal species. Paul and Trask⁵ of Yale University School of Medicine, for example, allege that freshly isolated poliomyelitis virus is thus altered by repeated inoculations into monkeys. In their hands the differences between the recently isolated or antihuman phase of this virus and the same virus after repeated passage through monkeys are not solely quantitative in character. New antigenic fractions have apparently been induced in the virus as a result of repeated animal passage, an evolutionary phenomenon reminiscent of the well confirmed antigenic "transformations" of type pneumococci⁶.

Current Comment

THE TREATMENT OF CARBON MONOXIDE ASPHYXIA

Carbon monoxide asphyxia has received so much publicity that an increasing number of investigators are offering new methods of treatment.¹ The proposed remedies are mainly respiratory stimulants.² The evidence offered for them is that animals asphyxiated to the point of failure of respiration survive if the drug is at that instant administered. Clinically the physician must apply the remedy at almost the exact instant at which respiration fails. If he arrives ten or even five minutes later, the victim will be beyond recovery. Owing to the fact that the respiratory stimulant drugs (such as lobeline or methylthionine chloride) have deleterious effects on the heart and circulation, the patient may be better next day if the drug is not administered. Many physicians fail to understand that asphyxia and failure of respiration are by no means the same, even if the one may lead to the other. A patient comatose from asphyxia, and likely to die some hours later, is often found breathing with even more than normal vigor. What he needs, and all that he needs, is removal of the carbon monoxide, restoration of the oxygen-transporting power of the blood and replacement of the carbon dioxide that has been lost during the development of asphyxia. None of these steps toward recovery, according to Henderson and Haggard, can be promoted to any considerable degree by any hypodermic medication,³ but they are all directly achieved by the inhalation of oxygen and from 7 to 10 per cent of carbon dioxide. This treatment is now so well established theoretically, and has saved so many hundreds of lives that it must still be considered the

method of choice. Since the introduction of the inhalational treatment of carbon monoxide asphyxia, the deaths from illuminating gas poisoning in New York City for the six years ended with 1932 have been as follows: 611, 570, 525, 435, 305 and 278. This is a striking demonstration of the effectiveness of this treatment.

METHYLENE BLUE IN TREATMENT OF EXPERIMENTAL CYANIDE POISONING

In the fumigation of ships with hydrogen cyanide gas, accidental cases of cyanide poisoning sometimes occur. Experienced fumigators have learned that persons overcome with this gas either die quickly or, when removed to the open air, recover completely in a relatively short time. When a sublethal dose has been absorbed, the progress of poisoning stops at once and recovery begins. There are borderline cases in which sufficient gas has been absorbed to stop respiration but not sufficient to inhibit completely other bodily functions. If artificial respiration is used in such cases, enough gas may be removed through the lungs so that breathing will be resumed. Since the intravenous injection of methylene blue has been advocated in the treatment of cyanide poisoning, Trautman¹ of the U. S. Public Health Service has carried out experiments to determine the value of these injections in animals poisoned by the inhalation of lethal or near-lethal doses of hydrogen cyanide gas. In a preliminary study he found that rabbits exposed to the gas to the point at which they stopped breathing subsequently recovered, but if the exposure was prolonged more than ten seconds after breathing stopped they always died. Guinea-pigs and white rats reacted differently. If they were kept in the gas to the point of cessation of breathing, they invariably died. Trautman then placed the animals separately in glass jars, which he covered with oiled paper fastened with cord around the top of the jar. A pipet was inserted into a small hole in the oiled paper and enough hydrogen cyanide allowed to run down the edge of the jar to give a concentration of the gas of 1 ounce per thousand cubic feet. The animal was observed until it breathed in a nearly lethal dose and then was quickly removed from the jar and treated by injections of a 1 per cent solution of methylene blue in physiologic solution of sodium chloride. An equal number of control experiments were conducted. Fifty-four guinea-pigs were thus exposed to hydrogen cyanide gas and twenty-nine of them were given intraperitoneal injections of methylene blue. Seventeen of the animals recovered in the average time of twelve minutes and twenty-seven seconds. Among twenty-five guinea-pigs that did not receive methylene blue injections, fifteen recovered in an average time of thirteen minutes and ten seconds. Among thirty-two white rats exposed to a concentration of the gas equal to one-half ounce per thousand cubic feet and then given intraperitoneal injections of methylene blue in a dose of 1 cc per hundred grams of body weight, twenty recovered in an average time of thirteen minutes and

forty-six seconds. Of thirty-two rats used as controls thus gassed but not injected with methylene blue, twenty-two recovered and ten died. Of eighteen rabbits exposed to a concentration of the gas equal to one-half ounce per thousand cubic feet and then injected with 1 cc per kilogram of body weight of methylene blue, fifteen recovered. Of the seventeen control rabbits exposed to gas but receiving no methylene blue fifteen recovered. Lautman concluded that injections of methylene blue solution were of no value in the treatment of animals that had absorbed by breathing lethal or near-lethal doses of hydrocyanic gas in a short period of time.

Association News

SELECTION OF HOSPITALS IN COMPENSATION CASES ARISING OUT OF INJURIES TO EMPLOYEES OF THE CIVIL WORKS ADMINISTRATION

The following instructions have been issued by the United States Compensation Commission relative to the hospitalization of employees of the Federal Civil Works Administration.

Please instruct each local administrator in your state as follows:

1 Employees of the Civil Works Administration who suffer injuries while in the performance of duty are entitled to necessary hospital care for the treatment of conditions due to such injuries. An injured employee shall be admitted to and returned in a hospital as long as hospitalization is necessary for the purposes of treatment or examination. The instructions herein prescribe the procedure to be followed in selecting hospitals for the treatment of these cases and the schedule attached shows the rates to be allowed for hospital care. In no event however should these instructions be construed so as to interfere with the prompt and adequate care of an injured employee.

2 Injured employees must be referred to federal hospitals when such hospitals are both available and adequate. It is not intended to utilize these governmental facilities for civil works employees to the disadvantage of other classes of beneficiaries that may be entitled to care in federal hospitals but that beneficiaries for whom the respective federal hospitals were primarily established shall have preference in the use of such hospitals. However maximum use should be made of any existing federal medical facilities that may be available.

3 (a) When federal hospital facilities are not available or adequate cases requiring immediate hospital care shall be sent to the nearest suitable hospital which desires to participate in the service at the rates specified in the approved schedule of rates. Public hospitals other than federal are not to be given preference.

(b) The following factors should be considered in determining suitability: the proximity of the hospital; type of service; e. g., whether the hospital is well qualified to handle the special type of case; and the general quality of service.

(c) You should secure advice as to the suitability of local hospitals from one or more of the following local sources: medical advisory councils which may already be set up under Rules and Regulations No. 7 of the Federal Emergency Relief Administration; hospital associations; hospital health or similar councils; county medical societies; boards of public welfare or health.

4 (a) All hospital care must be authorized in writing by the proper officials on the staff of the local Civil Works Administrator. Care of emergency cases should not be delayed for a written authorization but this must be furnished within forty-eight hours after admittance to a hospital.

(b) An authorized physician in charge of the treatment of an injured employee as a compensation patient when hospital care

is required may send the patient to a hospital of the physician's selection provided the hospital thus selected agrees to the approved schedule of rates. However, hospitalization in such cases must be approved in writing as provided in paragraph 4 (a).

5 The Commission reserves the right to have its medical representatives examine patients at the hospital and examine the records of these patients and to cause the patient's removal when the Commission considers it necessary in the interest of the patient or to prevent overcharge, or for other sufficient reason. Hospital records of these patients shall be open to inspection by representatives of the Commission.

6 The Commission in conference with representatives of the national hospital associations, has agreed on a basic rate for the care of injured Civil Works Administration employees in general hospitals exclusive of federal hospitals. This rate includes many items for which extra charges are usually made. A schedule of rates for other services which are not included in the basic rate has also been agreed to. The national hospital associations have agreed to notify their members of these approved rates and urge their full cooperation with the Commission. The approved schedule of rates is attached hereto. Charges for services previously rendered will be adjusted under this schedule. (See paragraphs 34 and 35 of Civil Works Administration Rules and Regulations No. 5 for instructions concerning submission of vouchers.)

7 Each local administrator must make adequate provisions for the transportation of seriously injured employees to obtain medical treatment by arrangements made in advance for each work project. This may be done by arrangements for the use of automobiles available at the project, by agreement concerning the use of local ambulance services or such other arrangements as may be feasible. Ambulance service provided by hospitals is covered in the approved schedule of rates.

U. S. EMPLOYEES' COMPENSATION COMMISSION

SCHEDULE OF HOSPITAL FEES AGREED UPON BETWEEN THE JOINT COMMITTEE OF THE AMERICAN, CATHOLIC AND PROTESTANT HOSPITAL ASSOCIATIONS, THE CIVIL WORKS ADMINISTRATION AND THE U. S. EMPLOYEES' COMPENSATION COMMISSION

A \$3.50 per diem rate for all hospital cases of injured employees of the Civil Works Administration will be general throughout the United States regardless of local hospital costs or charges. This rate will apply in general hospitals, exclusive of federal.

The following items will be included in the rate:

The use of a single room when necessary	
General medical and surgical care by the house staff	
Ordinary nursing	Material for plaster casts
Special diets	Colonic irrigations
Usual medicines	Hypodermoclysis
Usual dressings and surgical supplies	
Usual laboratory tests such as:	
Blood counts	Coagulation time
Sneakers	Hemoglobin estimation
Usual urine tests	Occult blood
Wassermann tests	Skin tuberculin tests
Precipitation tests for syphilis	Spinal fluid smears and cell counts
Widal tests	Sputum examinations for tubercle bacillus
Agglutination tests	Other usual bacteriologic tests
Blood typing	

Such physical therapy treatments as may be necessary for patients in the hospital.

Autopsies and reports of same when a patient dies in the hospital.

There will be no charge for medical or hospital reports unless an actual transcript of the hospital record is requested in which case charge for same will be made in accordance with the local public stenographers' rates.

Charges will be allowed for the day of admission, but not for the day of discharge or death.

In addition to the foregoing rate it will be permissible to make the following extra charges:

1 An operating room fee of \$5 for a minor operation and \$10 for a major operation. A general anesthesia fee of \$5 for a minor operation and \$10 for a major operation to include anesthetic service by a salaried employee of the hospital and the cost of the anesthetic.

2 Laboratory examinations of an unusual character such as complete blood chemistry, gastric analyses etc. may be charged for at a rate of from \$3 to \$5 according to the nature of the examination (which must be specified in the voucher submitted) \$3 being the usual charge allowed for such examinations and reports.

3 Fee for special nursing when necessary will be allowed in accordance with the local prevailing rate or when furnished by a salaried employee of the hospital, at actual cost.

4 X-ray examination will be paid for in accordance with the following rate the number of films and procedure for each fee being indicated by the description below.

	No of Films	Price
Ankle joint anteroposterior and lateral views	2	\$ 2 50
Arm humerus anteroposterior and lateral views	2	2 50
Bladder with injection anteroposterior views	1	5 00
Chest for pulmonary or cardiac diagnosis, plain	1	3 75
Chest, for pulmonary or cardiac diagnosis, stereoscopic	2	5 00
Clavicle posteroanterior view	1	2 50
Fibula anteroposterior and lateral views	2	2 50
Fluoroscopy, when required without film	1	1 00
Foot anteroposterior and lateral views	2	2 50
Forearm radius and ulna anteroposterior and lateral	2	2 50
Foreign body in eye location of (the fragment charted in three planes and its dimensions ascertained by the method of Sweet or equivalent as needed)		12 50
Gallbladder Graham technic including cost of dye	1	10 00
Gastro-intestinal tract complete x-ray study including fluoroscopy as needed		12 50
Hand anteroposterior and lateral views	2	2 50
Hip joint plain anteroposterior view	1	1 75
Hip joint stereoscopic anteroposterior view	2	5 00
Intestine barium enema, 14 by 17 films for position and outline as needed		7 50
Jaw upper or lower	1	2 50
Kidneys right and left for comparison 11 by 14 films as needed		5 00
Knee joint anteroposterior and lateral views	2	2 50
Leg tibia and fibula anteroposterior and lateral views	2	2 50
Iodized poppy seed oil injection for bronchiectasis etc including roentgenograms and interpretation as needed		12 50
Pelvis 14 by 17 single film, anteroposterior view	1	5 00
Pyelography, using iopax or similar preparation (including cost of drug)	4	10 00
Ribs plain view over suspected area 10 by 12 film	1	3 75
Scapula	1	2 50
Shoulder joint plain anteroposterior views	1	2 50
Shoulder joint stereoscopic anteroposterior views	2	5 00
Sinuses, frontal and ethmoid, anteroposterior and lateral views	2	5 00
Sinuses, mastoid right and left sides for comparison	2	5 00
Sinuses, maxillary anteroposterior and lateral views	2	5 00
Skull ventriculogram air injection as needed	2	7 50
Skull anteroposterior and lateral views	2	5 00
Skull stereoscopic	2	7 50
Spine cervical anteroposterior and lateral views	2	5 00
Spine dorsal anteroposterior and lateral views	2	5 00
Spine lumbosacral with coccyx anteroposterior and lateral views	2	5 00
Stomach barium or bismuth meal 14 by 17 film after ingestion four 8 by 10 films for detection of duodenal cap total of four 8 by 10 films including fluoroscopy	4	12 50
Teeth single film	1	1 00
Teeth each additional film up to and including five films	1-5	1 00
Teeth series (five films up to and including full mouth)	(over 5)	5 00
Thigh femur anteroposterior and lateral views	2	3 75
Ureters right and left for comparison	(1 or 2)	7 50
Wrist, anteroposterior and lateral views	2	2 50

5 Unusual expensive medication and appliances will be supplied at cost. This includes such items as oxygen administration (marked preference being given to the use of commercial oxygen), biologicals, prosthetic and orthopedic appliances when furnished by the hospital. Blood transfusions not to exceed \$5 per hundred cubic centimeters to donor and a hospital charge of \$5 for the transfusion as a minor operation will be allowed.

6 Ambulance charges when furnished by the hospital may not exceed a minimum rate of \$3 when the call is within a three mile radius of the hospital. An additional rate of 50 cents per mile beyond the three mile radius one way will be allowed.

7 Professional and other fees of persons not employed by the hospital are not included in this agreement.

8 Fees for hospitalization and prophylactic treatment of contagious diseases not ordinarily treated in general hospitals are not included in this agreement and should be subject to local regulation.

MEDICAL BROADCAST FOR THE WEEK

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8 55 to 9 o'clock central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

January 23 A Pioneer Health Educator
January 25 Cockroaches

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 8 55 to 9 10 o'clock over Station WBBM.

The subject for the week is as follows:

January 27 Man's Place in Nature

Talks over Network of the National Broadcasting Company

The American Medical Association broadcasts each Monday afternoon from 5 to 5 15 Eastern standard time (4 o'clock, central standard time). The subject for Monday, January 22, is "Are You Afraid, Too?" The speaker will be Dr W W Bauer, director, Bureau of Health and Public Instruction of the American Medical Association. The program is now being broadcast by the following stations:

WJZ	New York	WJR	Detroit
WBAI	Baltimore	WKYC	Cincinnati
WMAL	Washington	KDKA	Pittsburgh
WBZ	Boston	KWCR	Cedar Rapids Iowa
WBZA	Springfield Ma s	KOIL	Omaha
WSA	Syracuse, N Y	WREN	Kansas City Mo
WHAM	Rochester N Y	WENR	Chicago
WGAR	Cleveland		

Previous announcements of time and of stations taking the program have been superseded. Subjects and speakers for subsequent broadcasts will be announced weekly in THE JOURNAL.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Midwinter Clinical Courses—The third annual midwinter clinical course in ophthalmology and otolaryngology given by the Research Study Club of Los Angeles opened, January 15, to continue through January 26. Coincidental with this course is one on dissection and cadaver surgery, conducted by Dr John F Barnhill, for many years professor of surgery of the head, Indiana University School of Medicine, Indianapolis. In addition to Dr Barnhill, other members of the teaching staff for the course in ophthalmology and otolaryngology include:

Prof Anton Elschnig of the German University Eye Clinic of Prague Czechoslovakia
Dr Edward C Sewall clinical professor of surgery Stanford University Medical School San Francisco

Dr Hans Barkan clinical professor of surgery department of ophthalmology Stanford University Medical School
Dr Harry L Baum Denver

CONNECTICUT

State Society Confers Honorary Medical Degree—For the first time in 121 years, the Connecticut State Medical Society exercised its charter right to confer the honorary degree of doctor of medicine, January 5, when it bestowed this honor on Russell H Chittenden, LL D, professor emeritus of physiologic chemistry and director emeritus of the Sheffield Scientific School of Yale University, New Haven, the New York Times reports. The ceremony was a feature of the celebration of the sesquicentennial of the New Haven County Medical Association, which the Times describes as the parent of the state society chartered eight years later. In conferring the degree Dr Ralph A McDonnell, New Haven, president of the state society, said:

This honor now held by no living man is about to be conferred upon you in recognition of your valuable contributions to our knowledge of the human body and because of the inspiration derived from your instruction by many who later achieved marked success in the practice of medicine.

Dr Chittenden received his degrees of bachelor and doctor of philosophy at the Sheffield Scientific School in 1875 and 1880, respectively. He has been associated with Yale in a teaching capacity since 1875 and director of the Sheffield Scientific School since 1898, becoming emeritus professor and director in 1922. He is a member of many scientific societies, an honorary fellow of the New York Academy of Medicine and the author of several books on physiologic chemistry.

GEORGIA

Society News—Dr Ralph H Chanev, Augusta, addressed the Tenth District Dental Society at Augusta November 21, on "Infections of the Mouth and Their Relation to Diseases of Other Parts of the Body."—Dr Michael J Egan Jr Savannah, presented a paper on "Cure of Recurrent, Ventral

and Large Hernia by O. Fascia Repair Reports of Cases" —Speakers before the Sixth District Medical Society at Milledgeville, December 6, included Dr. William M. Crison Sandersville, on "Hodgkin's Disease." —At a meeting of the Fulton County Medical Society, December 7, Drs. Hal M. Davison and Mason I. Lowmce, Atlanta, discussed the treatment of arthritis with hyperpyrexia.

ILLINOIS

Society News—Dr. Frank Smithies, Chicago, spoke before the Will-Grundy County Medical Society, January 10, on "Pernicious Anemia and Newer Aspects of Treatment." —At a meeting of the Iroquois County Medical Society, January 11, Dr. Bernard Fantus, Chicago, presented a paper on "Therapy of Rheumatic Fever." —Dr. Elven J. Berkheiser, Chicago, spoke before the Peoria City Medical Society, December 19, on "Fractures of the Ankle Joint."

Chicago

Symposium on Cancer—Clarence C. Little, Sc.D., director, Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, and managing director, American Society for the Control of Cancer, will participate in a symposium on cancer before the Chicago Medical Society, January 31, discussing the "Recent Biological Advance in Cancer Research." Dr. Greenwood will speak on the "Early Diagnosis and Treatment." Dr. Little will address a public meeting in the afternoon at the Murphy Memorial Hall on "What You Can Do for Cancer Control." This session is sponsored by the women's auxiliary of the Chicago Medical Society.

Hospital News—A contract has been let for the construction of the new Henrotin Polyclinic Hospital, to be known as the Chicago Polyclinic. To be erected at a cost of about \$500,000, the new building will be six stories high and will have 100 beds. —The Women and Children's Hospital observed its seventieth anniversary, January 5, in conjunction with the fifth anniversary of the opening of its \$1,000,000 building. The staff is composed entirely of women physicians. The institution was founded by Dr. Mary Thompson to care for women and children of veterans of the Civil War during an epidemic of cholera. One of the two hospitals in the city at that time did not admit women patients and the other did not allow women physicians to practice, it was reported. Maud Slye of the University of Chicago was among the speakers in the anniversary program.

MASSACHUSETTS

Health at Lowell—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended January 6, indicate that the highest mortality rate (22.4) appears for Lowell, and the rate for the group of cities as a whole, 13. The mortality rate for Lowell for the corresponding week last year was 18.7, and for the group of cities, 13.6. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Psychiatric Awards—Two awards of \$100 and \$50 will be made by the New England Society of Psychiatry at its next spring meeting to the writer or writers of the best papers completed or published during the calendar year 1933, embodying research in psychiatry by young workers. Physicians, psychologists, social workers or others are eligible, and membership in the society is not a requisite. Writers who have once received an award are not again eligible. Seasoned writers, senior physicians, or heads of departments in which there are junior workers, while not inevitably excluded will not generally be regarded as eligible for the awards. Copies of articles or marked copies of journals in which the articles appeared should be sent to the secretary of the society, Dr. Harlan L. Paine, North Grafton, Mass., before February 1.

Course on Medical Bibliography—The Boston Medical Library is conducting a short course in medical bibliography during January and February which is designed primarily, to introduce medical students to the methods employed in prosecuting an investigation of medical literature, acquainting them with the sources of information and the technique of following through a research. In addition to a presentation of technical bibliographic study, consideration will be given to the history of the art of printing. The library is also planning a bimonthly exhibition of current medical literature, in abstract, supplemented in the case of more important articles by the originals. There is now on display in the library an exhibit of historical source material representing the development of the medical

book in manuscript and print and notable examples of the thirteenth, fourteenth and fifteenth centuries.

Bills Introduced—H. 31, to amend the law relating to the sale of poisonous drugs, proposes to require vendors of arsenic, atropin chloral hydrate, chloroform, corrosive sublimate, cyanide of potassium, Donovan's solution, ergot, Fowler's solution, oil of pennyroyal, oil of savin, oil of tansy, Paris green, Parson's vermin exterminator, phosphorus, prussic acid, "rough on rats," strychnia, tartar emetic, tincture of aconite, tincture of belladonna, tincture of digitalis, tincture of nuxvomica, tincture of veratrum viride, compounds of fluorine or carbolic acid to affix to the container a red label on which is printed in black letters the name and place of business of the vendor, the words "poison" and the name of an antidote. H. 118 to amend the medical practice act, proposes that in addition to the educational qualifications now required of applicants for licenses to practice medicine, applicants shall have completed satisfactorily two years of college work prior to admission to their respective medical schools. This additional qualification, however, is to apply only to applicants matriculating in a medical school subsequent to the date this act takes effect. H. 125, to amend the optometry practice act, proposes to define optometry as the employment of any methods or means other than the use of drugs for the investigation and diagnosis of any malfunctioning, defect, deficiency or deformity of the visual system and its appendages, for the purpose of adapting or prescribing lenses and/or prisms and/or ocular training for the correction, relief and aid of the visual functions. H. 128 proposes to forbid the admittance of unvaccinated children to private schools. H. 147 proposes to repeal the laws relating to narcotic drugs and to enact the uniform narcotic drug act. H. 160 proposes to authorize the sexual sterilization of idiotic, imbecile, feeble-minded or insane inmates of state institutions. H. 293 to amend the pharmacy practice act proposes that the provisions of the pharmacy practice act shall not apply to the manufacture or sale of patent or proprietary medicines which do not contain salicylic acid, barbituric acid, acetanilid, phenol, bromine, or their salts or derivatives. H. 294 to supplement the pharmacy practice act, proposes to make it unlawful for any person, firm or corporation, owning, managing or conducting any place of business, not a licensed drug store to use any combination of words or signs indicating that such place of business is a place where medicines are compounded.

MICHIGAN

Course in Psychiatry and Neurology—A graduate course in psychiatry and neurology will be conducted at the University Hospital, Ann Arbor, January 22-27. Participating lecturers will be Drs. Carl D. Camp, Albert M. Barrett, Leonard E. Himler, John M. Dorsey, Raymond W. Wagoner, Robert R. Dieterle, Konstantin Lowenberg, Udo J. Wile and Max M. Peet, all of Ann Arbor, Robert H. Haskell, Northville, Franz Alexander, Chicago, and Lawson G. Lowrey, New York.

Detroit's Health Record—The lowest death rate in Detroit's history was reached in 1933 with a rate of 8.3 per thousand of population, as compared with 8.7 per thousand in 1932, which at that time was the lowest recorded. There were 12,345 deaths in Detroit in 1933 as compared with 12,988 in 1932. A new low death rate of 3.4 per hundred thousand of population was recorded for diphtheria, as compared with 4.3 for 1932, and an average rate of 20 for the preceding five years. There has not been a case of smallpox in Detroit for more than two years, the last one having occurred in August, 1931. There were only 983 deaths from tuberculosis as compared with 1,052, giving the lowest rate (66.3) in the city's history.

MISSISSIPPI

Pediatric Society Organized—The Mississippi State Pediatric Society was organized in Jackson, November 8. Charter members of the association are Drs. Noel C. Womack, president, Franklin C. Riley, Meridian, vice president, Guy C. Jarratt, secretary, Guy C. Verner, John K. Bullock, Harvey F. Garrison, Jr., Harvey F. Garrison, Sr., of Jackson, Robert E. Wilson, Greenville, George L. Arrington, Meridian, Joseph E. Green, Laurel and William P. Robert, Vicksburg. Physicians in good standing of the Mississippi State Medical Association who limit their practice to pediatrics will be considered active members of the new organization, while physicians only interested in the specialty will be designated as associate members.

Bill Introduced—S. 43 proposes to amend the law forbidding the sale, barter or giving away of commodities intended for smoking containing cannabis indica, so as to forbid also the keeping or possessing of such commodities.

MISSOURI

Cancer Survey—A survey of cancer will be carried out in Missouri by the American Society for the Control of Cancer, according to the state medical journal, as a preliminary movement in a campaign against cancer quacks and fake cancer cures. In addition to collecting statistics on cancer fakers and their victims, all phases of the cancer problem in the state will be studied with a view to enabling the state board of health and cooperating agencies to establish a far reaching campaign of public instruction.

Reporting Contagious Disease—Individual physicians will now report all contagious disease directly to the state health department instead of to the county health officer as heretofore, in accordance with a newly adopted plan. Several counties have discontinued the services of their health officers, since the law governing their employment was revised at the last session of the legislature to make it optional and not mandatory. The state department believes that the new system will insure the accurate reporting of morbidity statistics. Cards procured from the U S Public Health Service will be furnished to physicians to be filled out and returned to the department each week. Weekly health summaries will be issued in those counties that maintain health officers.

Society News—At a meeting of the Gasconade-Maries-Osage County Medical Society at Mount Sterling November 23, the speakers were Drs Norman Tobias and Julius A. Rossen, St. Louis, on "Extragenital Infections" and "Diarrhea in Infants and Children" respectively. The Five County Medical Society was addressed in Malden December 6, by Drs Lee D. Cady, St. Louis, on "Emotions and Their Physical Symptoms," and Carliss M. Stroud, St. Louis, "Allergy and the Practitioner with Consideration of Emotional Aspects." Speakers before the Jackson County Medical Society, January 16, were Drs Charles C. Dennie and Morris Polsky on "An Efficient Method of Heat Treatment," and James R. McVay, "Paraneoplastic Abscess, with Special Reference to X-Ray Findings." At a meeting of the St. Louis unit of the National League for the Rehabilitation of Speech at the Central Institute for the Deaf, January 8, Lee Edward Travis, Ph.D., Iowa City, spoke on "Left-Handedness as a Factor in Speech Disorders."

NEW JERSEY

Graduate Lectures—The Medical Society of New Jersey in cooperation with Rutgers University and with the Bergen County Tuberculosis and Health Association is presenting a graduate course in Hackensack for members of the Bergen County Medical Society. All the speakers are from New York. Dr Charles Ward G. Crampton, spoke, January 5, on periodic health examinations. Dr Bela Schick, January 12 on communicable diseases, and Dr Marshall C. Pease, Jr. January 19, on tuberculosis in children. Coming lectures will be

January 26 Dr John Wyckoff, Jr. Heart Disease in General Practice
February 2 Dr Robert T. Frank. Endocrine Diseases
February 9 Dr Ascher Winkelstein, Recent Advances in Gastro Enterology

Regulations for Sale of Hypnotic Drugs—The state board of pharmacy has issued regulations for enforcement of a law passed by the 1933 legislature concerning the sale of hypnotic drugs. No barbitol, barbituric acid, malonyl urea or other compounds, derivatives or preparations thereof may be dispensed or sold at retail to any person except on prescription from a duly licensed physician, dentist or veterinarian. The law applies as well to preparations containing trional sulphonal, tetronal carbomal, paraldehyde or chlorbutanol. If such prescriptions are not to be renewed, instructions to that effect must be written or printed on the prescription. Constant or frequent renewal without the knowledge of the physician is considered a violation of the spirit of the law but the regulation does not prevent renewal if the drugs are known to be intended for persons suffering from disorders requiring frequent use. The regulations do not apply to preparations intended for external use if they contain other drugs which give them other properties than those possessed by the hypnotic drugs. In other words, if they are sold in good faith for the purpose for which they are intended and not for purposes of evading the law.

NEW YORK

Bill Introduced—S. 66 proposes to accord to hospitals, physicians and nurses treating persons injured through the negligence of another, liens on any rights of actions judgments or settlements accruing to such injured persons by reason of their injuries.

New York City

Symposium on Encephalitis—The annual meeting of the New York Academy of Medicine was held, January 4, with a symposium on encephalitis as the principal feature. Speakers were

Dr Ralph S. Muckenfuss, St. Louis, Clinical and Research Aspects of the St. Louis Epidemic
Dr James P. Ierke, Washington, Epidemiology
Dr Leslie T. Webster, Recent Research in the Disease
Dr Josephine B. Neal, Clinical Observations
Dr Frederick Tilney, Importance of Differential Diagnosis
Dr Thomas M. Rivers, Summary and Discussion

A portrait of the late Dr Thomas W. Salmon was presented to the academy and the report of the Thomas W. Salmon Memorial Committee was presented.

Koba Appears Again—Tsuneo Koba, a Japanese whose activities as an impostor were detailed in THE JOURNAL, Aug. 1, 1931, page 339, has recently been discovered acting as a junior fellow in surgery at Presbyterian Hospital, Columbia University Medical Center, using the name Akira Matuzaki. Koba was recognized by a physician from California who visited the hospital. Investigation in the records of the New York Police Department and the California Board of Medical Examiners proved his identity and he was dismissed after having served several months. Soon after the publication of the article in THE JOURNAL in 1931, Koba, who also used the name of Tsuneo Kuba, was arrested in New York after he had presented a fraudulent certificate in an effort to obtain a position as an intern. He pleaded guilty to forgery, Dec. 28, 1931, and was sentenced, Feb. 16, 1932, to an indeterminate term in the New York County Penitentiary (THE JOURNAL, March 26, 1932, p. 1094).

Professors Appointed—Following a recent meeting of the council of New York University, the following appointments were announced:

Dr Mills Sturtevant, professor of clinical medicine
Dr Robert P. Wadham, professor of clinical surgery
Dr Norman H. Jolliffe, assistant professor of clinical medicine
Dr Currier McEwen, assistant professor of medicine
Drs Paul E. Bechet and Samuel M. Peck, assistant clinical professors of dermatology and syphilology
Dr John Winston Fowlkes, Jr., assistant professor of otorhinolaryngology
Dr John W. Hammond, assistant clinical professor of pediatrics
Dr Sophia J. Kleegman and Thomas E. Lavell, assistant clinical professors of gynecology
Dr Oswald N. LaRonda, assistant clinical professor of medicine

Dr Warren Coleman, who had served in the department of medicine for fifteen years, was made professor emeritus of clinical medicine. Following the death of Dr Richard T. Atkins, Dr Wesley C. Bowers was appointed acting head of the department of otorhinolaryngology.

Dr Sherman to Receive Medal—Henry C. Sherman, Ph.D., Mitchell professor of chemistry, Columbia University, has been chosen by the New York section of the American Chemical Society to receive the William H. Nichols Medal for 1934 in recognition of his research on vitamins. The award will be made at a meeting of the Chemists' Club, March 9, at which Lafayette B. Mendel, Ph.D., Sterling professor of physiologic chemistry, Yale University, New Haven, Conn., and Charles A. Browne, Ph.D., of the U. S. Bureau of Chemistry and Soils, Washington, D. C., will speak. Dr Sherman has been engaged in research and teaching at Columbia for about thirty-five years. He is senior author of the American Chemical Society's monograph "The Vitamins" and author of "Chemistry of Food and Nutrition," "Food Products" and "Methods of Organic Analysis." In 1926, he was president of the American Society of Biological Chemists and in 1907-1908 served as vice president of the American Chemical Society. In the announcement of the award, the jury of selection observed that Dr Sherman in collaboration with other chemists has developed quantitative methods for vitamin research, which have been used all over the world in the study of the distribution of vitamins in nature, vitamin values of foods and processes of food preparation to conserve vitamin values.

NORTH DAKOTA

New Members of State Examining Board—Drs Archibald D. McCannel, Minot, Albert W. Skelsey, Fargo, and Lee B. Greene, Edgeley, have been appointed to the North Dakota State Board of Medical Examiners to succeed Drs Jesse W. Bowen, Dickinson, Clyde E. Stackhouse, Bismarck, and Frederick L. Wicks, Valley City. Other members of the board are Drs Harry F. Emert, Sarles, president, George M. Williamson, Grand Forks, secretary, William H. Long, Fargo, William F. Sihler, Devils Lake, Philip G. Arzt, Jamestown, and John E. Countryman, Grafton.

OHIO

Academy Approves Plan for Hospital Insurance—The council and board of directors of the Academy of Medicine announce approval of the hospital insurance plan proposed by the Cleveland Hospital Council, whereby hospital services will be provided to groups of employees on an insurance basis a maximum of three weeks' hospital service in one year to be provided at insurance rates of \$9 or \$7.20 a year, depending on the type of accommodation desired. The academy has adopted a resolution which is in part as follows:

WHEREAS The hospitals of Cleveland comprising the Cleveland Hospital Council have developed a plan of group payment for hospital care which includes as essentials of the plan the free choice of hospital by the patient and doctor, the free choice of physician by the patient, the distinct separation of attending physicians' fees from hospital charges, the maintenance of quality of professional services to hospital patients all of which are not and are not to be changed from present existing customs, and

WHEREAS This plan of group hospitalization is not to be established or operated by any insurance company or other organization or individual for profit but is to be promoted and operated by a nonprofit corporation over which the participating hospitals virtually have control and

WHEREAS In the formulation of such a plan the Hospital Council has consulted the Academy of Medicine in respect to all the provisions of such a plan relating to the professional services rendered to subscribers under the plan and has earnestly tried to fully protect the interests of the medical profession in the operation of the plan now therefore be it

Resolved That the Academy of Medicine of Cleveland and Cuyahoga County Medical Society appreciates the efforts which the Hospital Council of Cleveland has made to meet the objections to the general plan of group hospitalization held by organized medicine on ethical and economic grounds and believes that these efforts have been successful and be it

Resolved That so long as the principles and practices set forth in the prospectus and draft submitted this day are maintained the Academy of Medicine approves and endorses the plan and will cooperate toward its successful operation

In a published statement, Dr. A. A. Jenkins, president of the academy, explains the plan in part as follows: Opposition has been raised and will continue to be raised to any plan which attempt to interject a third party between the physician and his patient or which submit the medical profession to conditions which make it impossible for the profession to serve the public adequately and to maintain its scientific and economic independence or which interfere with the free choice of physicians by patients. The plan of the Hospital Council as proposed to us safeguards the patient and the profession against any of the interferences which are inherent in so many other insurance plans. It will not change the practice of medicine as it relates to the hospitals and will not substitute hospital practice of medicine for private practice of medicine, since the plan covers only hospital bed care as considered separate and apart from the service rendered by the physician. The major hospitals of Cleveland join together to present to the public an insurance plan of payment for hospital services which always necessarily bulk large in comparison with the limited income of certain groups. By joining together, the hospitals unitedly serve the community and obviate the adoption in Cleveland of small parallel competing insurance plans which bring about price cutting and service cutting chaos. The hospitals in adopting the plan have taken into consideration the possible effects of such a plan on the medical profession and have amended and outlined the plan to preserve the present adequate and essential elements of private practice as they relate to hospital practice. The Academy of Medicine as a branch of organized medicine last year approved the Minority Report of the Committee on the Costs of Medical Care, which called for the maintenance of private practice of medicine and reemphasized the principles which are promulgated in our resolution. The Minority Report further reemphasized that the medical profession in consultation with existing groups in the local communities should develop plans for providing health services to all classes of people in accordance with their ability to pay. The action of the board and the council of the academy consistently follows the suggestions of the Minority Report of the Committee on the Costs of Medical Care."

PENNSYLVANIA

Society News—Dr. Harry G. Noah, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, December 7, on diagnosis and treatment of pulmonary tuberculosis. Dr. William F. Rienhoff, Jr., Baltimore, addressed the Harrisburg Academy of Medicine, December 19, on hyperthyroidism.

Philadelphia

Osler Memorial Meeting—The section on medical history of the College of Physicians of Philadelphia and the Philadelphia Psychiatric Society held a special meeting in memory of Sir William Osler, January 9. Dr. Maude E. S. Abbott, assistant professor of medical research, McGill University Faculty of Medicine, Montreal, delivered an address on "Osler's Contributions to Medicine, Especially Heart Diseases

with Reference to His Canadian Period and Some Personal Reminiscences" and Dr. Truman G. Schnabel, discussed "William Osler's Association with the Philadelphia General Hospital."

Society News—A symposium on fractures was presented before the Philadelphia Academy of Surgery, January 8, by Drs. Hubley R. Owen, William Bates, Adolph A. Walking and Calvin M. Smyth, Jr.—Dr. John A. Kolmer and Miss A. M. Rule presented a paper before the Pathological Society of Philadelphia, January 11, on "Vaccination of Monkeys Against Acute Anterior Poliomyelitis, with Special Reference to Oral Immunization" and Dr. Louis Tait, on "Effects of Reticulo-Endothelial Blockade upon Antibody Formation."

RHODE ISLAND

Society News—Dr. Howard M. Clute, Boston, addressed the Newport Medical Society, December 4, on surgery of the upper part of the abdomen. Dr. John Ridlon was elected president—Dr. Paul I. Yakovlev, research fellow in neuropathology, Harvard Medical School, Boston, gave an address at the State Hospital for Mental Diseases, Howard, December 18, on "Neural Mechanisms of Epileptic Seizures."

GENERAL

Society News—Dr. Frank K. Boland, Atlanta, was elected president of the Southern Surgical Association at its annual meeting in Hot Springs, Va., December 12-15. Drs. John H. Neff, University, Va., and Edgar P. Hogan, Birmingham, Ala., were elected vice presidents and Robert L. Payne, Norfolk, Va., secretary, reelected. The 1934 meeting will be held in Sea Island, Ga.—The eleventh annual meeting of the American Orthopsychiatric Association will be held in Chicago at the Palmer House, February 22-24—Dr. Cyrus C. Sturgis, Ann Arbor, Mich., was chosen chairman of Section N (Medical Sciences) of the American Association for the Advancement of Science at its winter meeting in Cambridge, Mass., and Dr. Earl B. McKinley, Washington, D. C., secretary.—The forty-sixth annual meeting of the American Physiological Society will be held in New York under the auspices of Columbia University College of Physicians and Surgeons, Columbia, March 28-31. Dr. Arno B. Luckhardt, Chicago, is president.

Medical Bills in Congress—Bills Introduced S 2000 introduced by Senator Copeland, New York, proposes to prevent the manufacture, shipment and sale of adulterated or misbranded food, drink, drugs and cosmetics, and to prevent the false advertisement of food, drink, drugs and cosmetics. This bill it is understood has been introduced as a substitute for the so-called Tugwell bill, S 1944. S 1990, introduced by Senator McNary, Oregon, proposes to extend to contract veterans, including contract surgeons, of the Spanish American War, the Philippine insurrection and the Chinese Boxer rebellion the benefits to which veterans of the World War are entitled. S 2040, introduced by Senator Robinson, Indiana, and H. R. 6176 introduced by Representative Taylor, Tennessee, propose to reenact all public laws extending benefits to veterans that were repealed by an Act to maintain the credit of the United States Government, approved March 20, 1933. H. R. 6138, introduced by Representative Ransley, Pennsylvania, proposes to provide additional benefits for veterans. Among other benefits, it provides that any World War veteran employed in service between April 6, 1917, and Nov. 11, 1918, not dishonorably discharged, suffering from disability, disease or defect, who is in need of hospitalization or domiciliary care, and who is unable to defray the necessary expenses therefor, may be furnished necessary hospitalization or domiciliary care in any veterans administration facility, irrespective of whether the disease, disability or defect was due to service. A statement by the veteran that he is unable to defray the necessary expenses incident to hospitalization or domiciliary care must be accepted by the Administrator of Veterans Affairs as sufficient evidence of that fact. The following bills are identical in phraseology with the bill just discussed: H. R. 6152, introduced by Representative Connolly, Pennsylvania; H. R. 6156, introduced by Representative Rankin (by request), Mississippi; H. R. 6170, introduced by Representative Hope, Kansas; H. R. 6205, introduced by Representative Scrugham, Nevada; H. R. 6209, introduced by Representative Johnson, Oklahoma; H. R. 6212, introduced by Representative McLeod, Michigan; H. R. 6215, introduced by Representative Swick, Pennsylvania; H. R. 6222, introduced by Representative Hastings, Oklahoma; H. R. 6364, introduced by Representative Rogers, Oklahoma; H. R. 6365, introduced by Representative Jenkins, Ohio; H. R. 6468, introduced by Representative Berlin (by request), Pennsylvania; and H. R. 6374, introduced by Representative

Representative Swank, Oklahoma H R 6194 introduced by Representative Dunn Pennsylvania, proposes an increase in compensations and pensions for veterans, ex service men and widows of ex service men H R 6200, introduced by Representative McLeod, Michigan, proposes to eliminate injustices and discriminations inflicted upon disabled veterans and their dependents. It provides, among other things, that all veterans, honorably discharged, who require hospital treatment and who are not able to reasonably pay for their own treatment shall receive hospitalization under the auspices of the federal government H R 6206, introduced by Representative Underwood, Ohio proposes to establish a Department of Veterans' Affairs with a Secretary of Veterans Affairs at the head thereof, and to adjust and equalize pensions of veterans and widows and dependents of veterans Among other things it proposes to provide, within the limits of departmental facilities, domiciliary and hospital care, including medical treatment to honorably discharged veterans who served in active military or naval service for a period of ninety days or more, and to persons honorably discharged from the army navy marine corps or coast guard who served in the active military or naval service for a period of six months or more when such veteran or honorably discharged person is suffering from permanent disabilities or tuberculous or neuropsychiatric ailments, which incapacitates him from earning a living, and who has no adequate means of support It directs the Secretary of Veterans' Affairs to continue the hospital care of veterans properly admitted under the laws in effect prior to March 20, 1933, until such time as they may be discharged without jeopardizing their health or life The bill also proposes to establish a joint congressional committee to be known as 'Joint Committee on Veterans Affairs' whose duty it shall be to investigate the operation and effects of the federal system of pensions and other benefits to veterans and to render a report from time to time to the committee of the House and Senate having legislative jurisdiction over pensions and other benefits for veterans H R 6207 also introduced by Representative Underwood Ohio, is similar to the bill just discussed, H R 6206, with the exception that it does not propose to establish a Department of Veterans' Affairs H R 6376, introduced by Representative Black New York, proposes to prevent the manufacture sale or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, cosmetics and liquors

Government Services

Veterans' Administrator Protests Fee Reduction

The 15 per cent reduction in fees paid to physicians serving the Veterans' Administration on a fee basis has hampered the administration to such an extent that medical service may be adversely affected, according to a letter sent to the Comptroller General by Brig Gen Frank L Hines, Veterans' Administrator The administrator pointed out that these fees had been revised in December, 1932, before the reduction ordered in the economy law of March 1933 In response the comptroller said that he "appreciated the difficulties" confronting the veterans' administration, but that the law is plain and no exceptions may be made The condition has been aggravated, it was added by the situation abroad, where the state department has told the administration that it will no longer use its facilities to obtain medical service for veterans To this point the comptroller replied that it may not be necessary to apply the cut if a specific authorization is made for each case

Interns for U S Public Health Service

The United States Public Health Service is receiving during January applications for a second year internship beginning about July 1, from physicians not over 30 years old who have graduated from a class A medical college and who will complete one year's internship at an approved hospital prior to July, 1934 Applications are desired only from candidates who are interested in the service as a career and who wish to appear before a board of commissioned officers of the service for examination as to physical condition and general fitness and a written professional examination Appointments will be made to the extent of the number of vacancies available with the understanding that an opportunity will be afforded within about a year to take the regular corps examination Inquiries should be addressed to the Surgeon General, U S Public Health Service, Washington, D C

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec 23, 1933

Radiotherapy in England

Serious criticisms of the present position of radiotherapy in this country are made in a report of a committee of the Section of Radiology of the Royal Society of Medicine Greater importance is attached to radiotherapy abroad Our relative backwardness is attributed largely to the prevalent attitude of surgeons who regard radium and x-rays as a mere adjuvant to surgery, often considering resort to them only in advanced disease or for recurrences after operation The facilities for research in England, especially in radiation treatment, have been meager, owing mainly to lack of funds The committee is strongly in favor of treatment by a "radium bomb" of 4 Gm or more, basing this view partly on replies to a questionnaire to the heads of six important radium centers at home and abroad, only two of whom were opposed to this form of treatment, and these had no personal experience with it The committee recommends that a special radiotherapeutic hospital should be established in or near London, with a director assisted by an adequate resident and visiting staff The hospital should have not fewer than 100 beds, with ample supplies of radium and equipment for every form of roentgen treatment and examination It should possess ample facilities for research in all its aspects and have adequate arrangements for teaching and demonstration It should be an independent foundation recognized by and affiliated with London University Special technical recommendations are made for radium "bombs" of 4 Gm or more used over a minimum period of five years, and for x-rays of voltage ranging from 250,000 to 1,000,000 or more

The Education of Nurses

A memorandum to the General Council of Nursing on the preliminary education of nurses has been drawn up by Lord Moynihan and the medical teachers of the Leeds area against the proposal to relegate the teaching of anatomy, physiology and elementary hygiene for the state examination to the school period The signatories state that they represent a training school that may claim to have done much to advance and perfect the training of nurses in both its academic and its practical aspects They consider the proposal retrograde for the following reasons 1 The teaching would have to be given in a large number of schools instead of being concentrated in a small number of hospitals, as at present 2 The teachers in such schools would rarely, if ever, have a standard of practical experience comparable to those at present responsible 3 Such teaching would be entirely theoretical and divorced from contact with living persons, by which alone the use of such knowledge is explained by professional men and women and made fully understandable to pupils by their seeing the application of the facts in their daily work 4 Under the proposed system, headmistresses of schools who had no knowledge of the requirements of the nursing profession would select girls for training, and parents would spend money on what they would think gave a right of entry to the nursing profession But it is only practical matrons who themselves have shown that they have the requisite qualities for the profession that are competent to select They would have thrust on them imperfectly taught and often temperamentally unsuited girls

Sir William Whitla

Sir William Whitla emeritus professor of materia medica and therapeutics, Queen's University, Belfast, has died at the

age of 82 years. Though his name is not connected with any discovery or particular doctrine, he was known all over the English-speaking world by his textbooks. On leaving school he was apprenticed to a firm of pharmacists in Belfast, a training that gave him a competence for his work as a teacher which few physicians have enjoyed. On the termination of his apprenticeship he entered Queen's College Belfast, as a medical student. His career was brilliant. He began private practice in Belfast and before the age of 30 was appointed physician to the hospital. His first famous book 'The Elements of Pharmacy and Therapeutics' was an immediate success. It has passed through twelve editions and become a classic. In 1891 appeared his 'Dictionary of Treatment,' which was separately published in America and was translated into Chinese. The valuable feature of this work was that it did not consist of lists of remedies or citations of authorities but gave on every point the experience and considered opinion of a great physician. He had a genius for the teaching of detail.

PARIS

(From Our Regular Correspondent)

Dec 6, 1933

Increase in Students at the University of Paris

The growing accretions of students at the University of Paris, which, for a time, were viewed with favor as furnishing evidence of the growth of French culture, are beginning to awaken some anxiety. The lecture halls are becoming inadequate and it is becoming necessary to erect new buildings and to increase the number of professors. The total number of students, men and women, matriculated on the basis of scholarship, is 35,365, as compared with 33,821 the previous year which signifies an increase of 1,544. The number of foreign students, which in 1932 was 7,504, declined in 1933 to 7,490. The number of women students has increased from 9,252 in 1932 to 9,809 in 1933. The studies that attract the most women are those pertaining to law and belles-lettres in which faculties in 1933 respectively 305 and 352 more women students were enrolled than the previous year. Scientific studies attracted 100 fewer women students in 1933 than in 1932 in the field of medicine, and 61 fewer in the pure sciences. With regard to the total number of medical students enrolled in the French faculties, the minister of public instruction has furnished statistics that show an increase since the war. The roster of students enrolled in the faculties of medicine in January, 1914 was 8,533, of whom 1,368 were foreigners. These figures include men and women students studying for the degree of doctor of medicine, for the title of public health officer, and for the diploma of dental surgeon. The number of students enrolled in the faculties of medicine, the end of December, 1932, was 19,220, of whom 4,285 were foreigners. These figures include men and women students studying for the degree of doctor of medicine, for the diploma of dental surgeon and for the diploma of midwife. The number of foreign students at the Faculté de médecine de Paris, which in 1932 was 3,232, rose in 1933 to 3,516, an increase of 184. It is this fact that disturbs the French students most, and even the French physicians for these foreigners, for the most part, instead of returning to their native country, succeed in circumventing the laws and in practicing medicine in France, where there is a plethora of physicians, many of whom find it difficult to earn a respectable living.

Scandalous Wasting of Public Funds in Organizing a Sanatorium Village

Considerable stir has been aroused in medical and political circles by the creation, under the auspices of the Association des blessés du poumon de la guerre, of a sanatorium village for the lodging of its members and their families. Mr. Delsuc

who had been a minor employee in the mayor's office of a town in the Dordogne, founded the association, of which he serves as president, and then he established a special journal to promote its cause. He bombarded the various ministries to secure increases of pension for his comrades and propagandized members of parliament many of whom have an ear to the ground if there is any threat of reprisal directed by the leagues of ex-service men. Thus encouraged, the Association des blessés de la guerre decided to create a sanatorium city in the native haunts of its president, Mr. Delsuc, who kindly consented to choose a suitable site, ordered the construction work and the equipment, and secured from the chamber of deputies an appropriation of 52,000,000 francs (\$3,120,000). The village is still uncompleted and Mr. Delsuc now requests a further appropriation of 22,000,000 francs (\$1,320,000). The minister ordered an inquiry, which is not being pushed rapidly. The medical syndicates, however, became aroused and instituted an inquiry, which took on an exclusively professional character so as to preclude any intrusion by politicians. A committee appointed by the Union des syndicats médicaux proceeded under the direction of Dr. Cibric, the general secretary, to the sanatorium village, which has been christened with the pleasing name of 'Chirvivore.' The committee was cordially received, inspected carefully all the installations and published, in the *Sécle médical*, its report, which revealed a startling state of affairs. Mr. Delsuc had chosen, without consulting the sanitary commission, which is the regular practice in such cases, a humid and swampy site in a valley that lacks the hygienic qualifications for sanatorium purposes. The village consists of 186 separate pavilions, each containing two apartments, and a large hotel, with 150 rooms, furnished and equipped with the conveniences of a palace. No serious precautions had been taken for the isolation of the tuberculous. Instead of using electric current already available and which in abundance of waterfalls in the region makes reasonable in price, Delsuc had had an immense thermo electric plant constructed, at an enormous cost. The pavilions and hotel, as completed, will accommodate 522 tuberculous patients. Delsuc's project was supposed to accommodate 1,500 patients and also numerous physicians, nurses, administrative officers and laboratory workers. In the face of such a waste of public money, the medical profession vigorously protested. Delsuc replied with feeble attempts to justify himself, all of which served only to demonstrate his incompetence. The minister is placed in an embarrassing position and hesitates to grant the 22,000,000 francs (\$1,320,000) requested by Delsuc for the completion of the project. The project remains, however, incomplete, and the whole cost will be greatly enhanced by reason of the vast installations calculated to serve a population three times as large.

BERLIN

(From Our Regular Correspondent)

Dec 4, 1933

Statistics on Obstetric Operations

Statistics are often deceptive as they are often based on meager data. Statistics compiled by the public health service on obstetric operations performed in the city of Hamburg will have some value in view of the amount of material available. In Hamburg which has a population of 1,100,000 a total of 5,391 births were completed with the aid of an operation during the three years 1929-1931. Since during that period, there were 46,401 births (inclusive of stillbirths), there were 1161 obstetric operations per thousand births. The figure 5,391 represents 3,654 obstetric operations such as the use of forceps, version, extraction, embryotomy, perforation, induced premature birth and cesarean section corresponding to 787

per cent of the births, and also 1,737 cases with operative aid in such complications as hemorrhages, placenta praevia, eclampsia, and postnatal complications.

Compared with the prewar period, the number of births completed by operation shows a marked increase, for instance, during the period 1910-1911, a total of 3,488 operations were performed in Hamburg, which included the complications of the birth process but did not include aid given in hemorrhages, and represented 8.05 per cent of the total number of births. Aside from the birth complications, obstetric operations were performed in 2,854 cases, or in 6.50 per cent of the births.

The distribution of the obstetric operations has undergone a change as compared with the prewar period. Podalic version has declined to about half of its prewar frequency. Artificial induction of premature birth was not reported in 1929-1931 in a single instance. Embryotomy has increased from 2.1 per cent to 3.3 per cent. Cesarean section has increased to an even greater extent. During the period 1876-1880, cesarean section occurred only once in a thousand obstetric operations performed in Hamburg. In 1910-1911 the proportion increased to 13 per thousand, in 1929-1931 the proportion rose to 176 per thousand. For the most part, cesarean section was substituted for version. A period of fifty years has brought a 350 fold increase in the use of cesarean section. In the early history of the revived operation (for example, in 1881-1885), 75 per cent of the mothers succumbed to the operation, in 1910-1911, only 18.2 per cent, and the mortality has since decreased steadily.

The mortality of other obstetric operations has likewise declined, although not to the same extent. The percentage of stillbirths resulting from the use of forceps has changed the least (1910-1911, 6.0 per cent, 1929-1931, 5.1 per cent). With respect to version, the decline in mortality over this period has been something more than one third (from 38.5 per cent to 24.5 per cent), as regards extraction, a little more than one fourth (from 20.9 per cent to 15.1 per cent). Taking obstetric operations as a whole, the danger of a stillbirth has declined from 18.0 per cent to 13.4 per cent, or about one fourth, which has been brought about chiefly through the improvement in the technic of cesarean section.

The complications of labor have become more frequent. 1910-1911, 14.5 per cent, 1929-1931 (without hemorrhages), 19.7 per cent. Various complications make up the increase, but particularly eclampsia which increased from 0.09 per cent to 0.34 per cent.

With respect to stillbirths, in 1910-1911, 61.5 per cent of the babies were born dead in association with placenta praevia, in 1929-1930, only 19.4 per cent. In eclampsia, the infant mortality has declined from 25 per cent to 12 per cent.

The marked increase in the number of obstetric operations is due to the easily obtainable operative assistance, as is shown by a detailed statistical comparison with Norway with its sparse population.

Reorganization of the Red Cross

The pending reorganization of the German Red Cross is now an accomplished fact. With the approval of the federal government, the president of the Red Cross drew up a new constitution, which, in keeping with the spirit of the national-socialist state, is designed to effect a firmer union of all societies and forces that merged in 1921 to form the German Red Cross. The new constitution defines more definitely the duties of the Red Cross: collaboration with the official sanitary service of the army in time of war, and the rendering of aid in public disasters and internal disorders. Among its primary tasks are the recruiting, training and equipping of the members of the sanitary units and the women's auxiliaries and voluntary service in promoting the public welfare (in epidemics and the

like) in connection with public welfare work. The German Red Cross is composed of the constituent societies of the various *lander*, which correspond to the recently established *stadtholderships* of the reich. The German Red Cross is under the control of the president of the reich. The administrative authority is vested in the president, the presidial council and the superior council. The president is appointed for four years by the president of the reich, the vice president is chosen by the federal minister of the interior. The president of the Red Cross appoints the counseling bodies of the head administration. Federal administrators are appointed for the most important branches of the Red Cross service. Only the head officials receive a salary. Following this reorganization, the president in charge, von Winterfeld, resigned and the former reigning duke, Karl-Eduard of Saxony-Coburg-Gotha, who for many years has been an adherent of national socialism, has been appointed his successor.

Eightieth Birthday of Professor Sudhoff

Prof. Karl Sudhoff, historian of medicine, celebrated his eightieth birthday November 26. Early in his career, while a country practitioner, he published studies on Paracelsus. He devoted his energies not only to scientific research but also to the history of medicine and he had created a special section of the history of medicine at the sessions of the *Gesellschaft Deutscher Naturforscher und Aerzte*, which was followed in 1901 by the founding of the German Society for the History of Medicine, Natural Sciences and Technic. He was called to the chair of the history of medicine at the University of Leipzig, where he created an instruction and research center that became recognized as a model. He devoted his chief energies to research on Paracelsus, whose medical writings he is publishing in an imposing edition, which is now almost complete. As a special honor, he recently received the Goethe Medal by authority of the president of the reich. His pupil and successor, Prof. H. E. Sigerist, is at present a member of the faculty of Johns Hopkins University, Baltimore.

Societies Merge

The German Orthopedic Society and the *Deutsche Vereinigung für Kruppelfürsorge* (Professor Gocht of Berlin is chairman of both organizations) have been united to form a federal merger, as a member of the *Reichszentrale für Gesundheitsführung*, operating under the federal ministry of the interior. The director is Dr. Bartels of the federal ministry of the interior, the secretarial duties have devolved on Dr. Eckhardt, the acting director of the *Vereinigung für Kruppelfürsorge*.

Prof. August Martin's Death

August Martin, gynecologist, of Berlin, has died at the age of 86. A pupil of his father, Eduard Martin, he occupied for many years the chair of gynecology at the University of Greifswald until he received a call to Berlin. In obstetrics, his fame was based chiefly on his operation in extra-uterine pregnancy continuing to term, and on his method for the extraction of the aftercoming head, known as the Martin maneuver. In gynecology he is best known for his improvements in the technic of vaginal operative methods. His textbooks have been translated into several languages. He was the founder and until his death one of the editors of the *Monatsschrift für Geburtshilfe und Gynäkologie*.

Eugenics at the University of Berlin

A new chair of race hygiene, or eugenics, has been created in the medical faculty of the University of Berlin, and Prof. Fritz Lenz, who comes from the University of Munich, will be the first incumbent. Lenz (who is 56 years old) has been studying eugenic problems for more than twenty years.

ITALY

(From Our Regular Correspondent)

Oct 31, 1933

Survey of Hospitals in Italy

The Central Bureau of Statistics made a survey of all the hospitals and sanatoriums at the close of 1932. The statistics do not include the military hospitals, the ambulatoriums and the infirmaries of prisons and colleges. The preliminary report of this investigation reveals that, on Dec. 31, 1932, there were 2086 hospital institutions in Italy including both public and private, or about five for each 100,000 inhabitants. The total bed capacity of these institutions was 238,511 or an average of 114 beds per institution. The number of beds showed an increase of about 76 per cent as compared with the total reported for Dec. 31, 1907. Lombardy leads with 308 hospitals and sanatoriums, or 148 per cent of the total for Italy. In 1932 the number of admissions was 1,119,003, the total number of days of hospitalization being 65,515,022.

The Apulian Academy of Science

The Accademia Pugliese di scienza met recently at Bari under the chairmanship of Prof. Priolo Gufami. Miselli spoke on late syphilitic arthropathies, pointing out that osteoarthritic deformations in children is a frequent manifestation of congenital syphilis. Syphilitic osteoarthritides of the hip, congenital or acquired, may present variable pictures, which often are confounded with other osteoarthritic types and which may present polyarthritic and symmetrical forms.

Russo discussed polysinusitis with orbital complications and contended that in the pathogenesis of this infection one should first examine the ethmoidal sinus, which is generally the basal sinus of polysinusitis.

Milella reported the results of observations in the ambulatorium on amebiasis instituted in the Clinica medica of Bari. In seventy-five cases there were positive results with regard to various types of parasites, among which were *Lamblia intestinalis*, *Endamoeba coli* and *Cercomonas*. *Endamoeba histolytica* was found in twenty-four cases, in which were observed pulmonary abscesses, hepatitis and types of a dysenteric nature. Some persons were found to be carriers of *Endamoeba histolytica* although they presented no intestinal manifestations.

Attimonelli spoke on the para-immunity existing between tuberculosis and anthrax. Of guinea-pigs previously infected with tuberculosis and later inoculated with anthrax, 55 per cent survived, whereas all the controls died. The author thinks that this great resistance is not due to bacterial antagonism but to multiple humoral and cellular changes.

Adenoids and the Sex Glands

Professor Citelli called the attention of the Societa medicochirurgica di Catania to the effect of adenoids on the development of the sex glands. Some time ago, he demonstrated that adenoids may provoke cellular changes in the anterior lobe of the hypophysis. At puberty, these changes may provoke dysfunction of the sexual hormones, both male and female, and sometimes may provoke the adiposogenital syndrome of Frohlich. He described, from records of cases occurring from 1917 to 1929, examples of hypophyseal feminism, arrest of development of the sexual organs, and frigidity, in which improvement or a cure was effected by either the removal of the adenoids or in association with hypophyseal therapy. He has observed similar cases recently.

Malta Fever

At a session of the Consiglio superiore di sanita Professor Vernoni of the University of Rome discussed Malta fever. During the first six months of the current year there developed in certain provinces of Italy various foci of Malta fever in

man, and also in birds and cattle. The commission appointed by the Consiglio superiore di sanita made a study of the various factors inherent in the problem.

BUENOS AIRES

(From Our Regular Correspondent)

Nov. 3, 1933

The Congress of Surgery

The Fifth Argentine Congress of Surgery was inaugurated, October 8. Dr. F. Finocchio was the president. In the mornings, operative clinics were given in the hospitals, in the afternoons, sessions were held and, in the evenings, films were shown. There was an exposition of surgical instruments and apparatus, most of them manufactured in Argentina. There were many foreign physicians present. The first topic discussed was "Treatment of Acute Intestinal Occlusion." Drs. D. Prat of Montevideo and D. del Valle of Buenos Aires, the official speakers, emphasized the advisability of an early roentgen examination of the patient for an early diagnosis and treatment. The second topic discussed was "Treatment of Fractures of the Elbow." Drs. Rezende Puchta of São Paulo and N. Ingbarache of Buenos Aires were the official speakers. The third topic was "Surgery in Diabetes." Dr. Rodriguez Villegas, the official speaker, emphasized the importance of a careful medical treatment, the administration of insulin, oral hygiene, the hydration of the patient and care in the postoperative period. Drs. J. Arce and M. Viñas were elected president and vice president respectively of the next congress in 1934. The official topics to be discussed in the coming congresses, 1934 and 1935 will be "Treatment of Nontuberculous Suppuration of the Lung" and "Treatment of Empyema" and "Treatment of Acute and Chronic Osteomyelitis," respectively.

Proper Diet for the Average Person

Dr. P. Escudero, director of the Instituto Municipal de Enfermedades de la Nutricion of Buenos Aires, has recently published in a daily paper, *La Prensa* of Buenos Aires various articles on the proper diet for the average person. A large part of the data appearing in his articles were taken from the work of McCollum and Simpson. He believes that the diet in Argentina is insufficient in calcium. He considers it advisable to establish a school of dietitians in Argentina to be in charge of the preparation of food in the municipal hospitals. He also suggests the establishment of municipal dining rooms for workmen in which they may obtain proper food at moderate expense. The custom of workmen eating in their own homes, the meals prepared by their own wives is expensive, unwholesome and wasteful. It would be much better if large public kitchens with a capable personnel and suitable utensils were established, in which the aim would be less waste and better food. Dr. Escudero has recently returned from a twenty-day stay in Rio de Janeiro, where he gave lectures on dietetics.

The Hypophysis and Metabolism

In a lecture before the Academy of Medicine of Buenos Aires last August, Dr. Houssay stated that the anterior lobe of the hypophysis may have an influence on the basal metabolism but this is only through the thyroid. In twenty-seven dogs deprived of the hypophysis (twenty-two of which were studied in Buenos Aires) there was a metabolic decrease averaging 16 per cent. Dogs deprived of the hypophysis show only an incomplete hypothyroidism, because if the thyroid is removed the metabolism drops still more—to 25 per cent below normal. By removing only the thyroid of the dogs the same drop in the metabolism is obtained and the following removal of the hypophysis does not modify further the metabolism. The injections of extract of the anterior lobe of the hypophysis stimulate the thyroid.

and produce in the dog an increase of the metabolism, which may rise to +128 per cent. In dogs deprived of either the thyroid or both the thyroid and the hypophysis the injection of extract of the anterior lobe of the hypophysis either fails to increase the metabolism or increases it but slightly. The hypophysis, therefore, does not have a direct action on the basal metabolism of the dog but an indirect action on it, through the thyroid. The lesion of the tuber cinereum in dogs produces genital atrophy and enormous adiposity in the animals. The metabolism was studied in twenty-two of these cases (eleven of Grafe, five of Mazzocco and six of Solari). In this group thirteen dogs presented decrease of the basal metabolism. Nevertheless, in several of the animals there was neither atrophy nor flattening of the thyroid epithelium, which are observed in dogs deprived of the hypophysis. The cause of the decrease of the metabolism in dogs with lesions of the tuber cinereum is still unknown. The specific dynamic action is normal in dogs deprived of the hypophysis (six of Artundo, nine of Mazzocco and five of Houssay and Artundo). The removal of either the thyroid or both the thyroid and the hypophysis produces a diminution of the specific dynamic action. Dr. Houssay stated in his lectures that the anterior lobe of the hypophysis contributes to the production of sugar and recesses to its consumption by the organism. In the Buenos Aires letter in *THE JOURNAL*, October 7, the translation of some sentences was incorrect. In the original it was stated that Dr. Houssay said that the principal function of the hypophysis is on metabolism while the translator added the words "of the carbohydrates." On page 1167 the words "in the production" were omitted. He also stated that the hypophysis plays an essential role in the metabolism of the carbohydrates which is only exceeded by that of the pancreas and that of the liver. It was interpreted as appeared on page 1168 of *THE JOURNAL* that the role of the hypophysis exceeds that of the pancreas and that of the liver.

Prizes Awarded

At the commencement exercises at the Faculty of Medicine of Buenos Aires, October 6, the following prizes were awarded: the Wilde award to Dr. T. Reza for her work on "Infantile Delinquency in the United States and in Argentina"; the Wernicke prize to Dr. J. Bacigalupo for his work on "Fasciola Hepatica in Argentina"; the prize for the best paper to Dr. J. Diez for his work on 'Surgery of the Lumbar Sympathetic'; the prizes for the best theses presented in course of 1932 to Drs. A. E. Roffo for his work "Biology of Ultrashort Waves," A. Tachella for his work on "Basal Metabolism in Surgery" and F. J. Manfredi for his work on 'Experimental Duodenal Ulcer'; the Luis Guemes prize to Dr. A. Camauer for his work on "Clinical Studies of Diseases of the Tubero-Infundibular Region"; the A. Centeno prize to Dr. F. de Elizalde for his work on "Werthoff's Disease," and the Lagleyze prize to Dr. G. von Grollman for his work on 'Diathermy in Ophthalmology'.

National Congress of Medicine

The fifth National Congress of Medicine will be held at Rosario, Santa Fe, in July, 1934, under the auspices of the national government. Amebiasis will be the official topic. The congress will meet at the Faculty of Medicine of Rosario and at the Centenario Hospital.

University News

The following speakers have recently lectured in Montevideo: Drs. E. Hug on 'Treatment of Poisoning with Hydrocyanic Acid by Sodium Nitrite and Sodium Hyposulphite'; B. A. Houssay on 'Hypophysis and Endocrine Glands'; and J. Govea on 'Sclerosis of the Pulmonary Artery.' Dr. Faure Fremiet of the College de France gave eight lectures on 'The Physio-

chemistry of the Cell', Drs. Cerrutti of Rosario on "Endocrine Functions of the Semiferous Canals," Lambette of Antwerp on 'Osteosynthesis,' and Hahn of Berlin on hygiene. The following speakers from Montevideo have recently lectured in Argentina: Drs. Velazco Lombardini on cardiology, Surraco on urology and Garcia Otero on diseases of the lung.

Lectures by Foreign Professors

As a result of the economic depression, few foreign professors have been invited by the faculties of medicine of Buenos Aires to give lectures. However, lectures in the near future are expected to be given by Drs. Lambottel of Antwerp, Filipo Bottazzi of Naples, Faure-Fremiet of Paris and M. Hahn of Germany.

Personal Items

Dr. E. Hug has been appointed professor of pharmacology at the Faculty of Medicine of Rosario—Dr. E. Finochietto was appointed honorary professor to the Faculty of Medicine of Buenos Aires—Drs. J. Arce and A. H. Roffo were appointed representatives of Argentina to the International Congress of Cancer, recently held at Madrid—Dr. B. A. Houssay has been appointed to speak on the functions of the hypophysis at the "Jornadas Medicas," a medical week, which will be held at Brussels, in June 1934.

Dr. Lignieres Is Dead

Dr. J. Lignieres came from Paris to Argentina in 1898 to be the director of the Instituto Bacteriologico of the Association of Argentina Farmers. Since then he has also held the following positions: director of the Instituto Bacteriologico of the National Department of Agriculture, professor of bacteriology on the Veterinary Faculty and member of the National Academy of Medicine. His most important studies were on hemorrhagic septicemia. He isolated an actinobacillus. He made studies on trypanosomiasis and tuberculosis. Recently he showed open opposition to the extensive use of Calmette antituberculous vaccine. His last studies are those related with immunization against aphthous fever.

RIO DE JANEIRO

(From Our Regular Correspondent)

Nov. 5, 1933

Opening of the Most Complete Hospital in Brazil

The Penitencia Hospital, which is the best equipped hospital in Brazil, was opened October 29. It has been under construction for five years and cost about eight million dollars. This elegant hospital is erected on a tract of more than eight thousand square meters in one of the most beautiful spots in Rio. It has a right wing for women and a left wing for men, connected by a central block giving the building the shape of a letter H which facilitates access to all departments. On the ground floor there are a splendid hall in colored and white marble and various consultation offices for physicians. Here also are the administration offices and the well equipped sections for the specialties. There is a most complete roentgen department, with modern apparatus. There is a section devoted to skin diseases and syphilis. Rooms are equipped for ophthalmology, diathermy, otorhinolaryngology and odontology. The electric power plant of the building furnishes 600 kilowatts. On the upper floors are wards, some of eight and some of four beds, all equipped with apparatus that raises or lowers them easily; a section of private rooms with six large apartments and thirty-eight small rooms, thirteen utility rooms, four dining rooms, four linen rooms, four recreation rooms, an office for the director, waiting rooms and finally, on the upper floor of the central part of the building, the section of surgery with a central operating room faced with opaline material and receiving its electrical illumination from a system of lenses.

that converge the light toward the center. All ventilation and refrigeration is effected by machinery installed on the roof. To the side the operating room communicates with the bath, anesthesia, sterilizing and surgical equipment rooms. There are also four small operating rooms. The section of major surgery of the new hospital is one of its most admirable and complete installations. On the roof there is a garden for the recreation of patients. Enamel, opaline, marble and crystal produce a mellow interior effect. The illumination shows good taste and excellent adaptation. Without doubt the Penitenciar Hospital is one of the most beautiful monuments in Brazil.

Brain Abscess

Within three months Dr. David de Sanson has reported to the National Academy of Medicine a second case of brain abscess of the frontal region. His patient is on the way to recovery. He took the occasion to review the first case which he presented May 11 and to show the patient entirely cured. Whereas in the first case, the classic symptoms of cranial hypertension imposed an immediate operation, in the second case it was possible to wait the evolution of the abscess and to intervene at the opportune moment. In the second case the cause was also a frontal sinusitis with osteomyelitis much more extensive than in the first case. Besides all the external table of the frontal bone, a large part of the internal table laterally was also removed and the meninges were widely exposed. In the two cases the collection of pus attained a volume of between 150 and 200 cc.

Influence of Economic and Social Factors on Physical Development of Children

Before the Medical and Surgical Association of Minas Gerães, as reported in the *Brazil-medico* October 7, Dr. Fernando de Magalhães Gomes lectured on his study of the physical development of children, in which he was guided by the determination of the four indexes of Pirquet, Palmer-Brenton, Pignet and Quetelet. The index of Palmer-Brenton merits consideration because of its biologic foundations and practical value in indicating the degree of osseous development. From a knowledge of these indexes, from the physical development and from the biotype, the pediatrician will be enabled to draw conclusions concerning the feeding of children. In the 470 children examined, the indexes showed extremely low figures in the poor classes. Dr. Magalhães Gomes attributes a large part of malnutrition to the defective feeding of children. His investigation showed that the feeding is deficient especially in proteins. The importance of milk as one of the fundamentals affecting the physical development of children was pointed out by the author. The graphic study of the development of the stature obtained by the author and by Dr. Ernani Agricola in 7000 children calls attention to the pronounced increase in height of the children of Minas Gerães between 9 and 10 years which has never been observed in the mulatto children of São Paulo and Rio.

Marriages

WILLIAM F. HEALY, Evansville Ind. to Miss Ruth Gresham of Logansport, Nov. 15, 1933.

EARL W. BAILEY, Bunker Hill Ind., to Miss Mildred M. Fish of Toledo Ohio, Nov. 29, 1933.

ALBERT RUFUS SHELDON to Miss Grace Glidden both of Highland Park Ill., Dec. 15, 1933.

HOWARD WAKEFIELD to Miss Thelma I. Roach both of Chicago, Dec. 31, 1933.

JOHN HERMAN LONG, Baltimore, to Miss Eleanor Porter Legg Dec. 21, 1933.

SILVAN WILLIAM SIMON to Miss Jeanne Rice, both of Chicago January 5.

Deaths

Christopher Sumner Witherstine, Philadelphia, College of Physicians and Surgeons, Medical Department of Columbia College, New York 1878, formerly lecturer on therapeutics Temple University School of Medicine, visiting physician to the Home for Aged, Little Sisters of the Poor, 1880-1889 Germantown Almshouse, 1880-1881 and the Germantown Hospital, 1881-1883 foreign associate member Societe Francaise d'Hygiene de Paris, author of 'International Pocket Medical Formulary', associate editor of *Annual of the Universal Medical Sciences*, 1888-1896, *Sajous' Annual and Analytical Encyclopedia of Practical Medicine* since 1898, aged 79, died, Dec. 25, 1933 in the Presbyterian Home for Aged Couples and Aged Men, of arteriosclerosis and hypertension.

Leroy Crummer Los Angeles Northwestern University Medical School Chicago 1896 member of the House of Delegates of the American Medical Association 1917, 1919 and 1920, clinical professor of medical history and bibliography University of California Medical School and professor of the history of medicine, University of Southern California School of Medicine professor of medicine University of Nebraska College of Medicine, Omaha 1919-1925 when he became emeritus professor served during the World War, formerly on the staffs of St. Joseph's and Presbyterian hospitals Omaha author of "Clinical Features of Heart Disease" associate editor of *Annals of Medical History*, aged 61, died, January 2 of heart disease.

Howard Davis Haskins Portland Ore., Western Reserve University Medical Department, Cleveland 1895 professor of biochemistry, University of Oregon Medical School, formerly assistant and associate professor of organic chemistry and biochemistry at his alma mater author of "Organic Chemistry" and co-author of "A Textbook of Laboratory Diagnosis", aged 62, died Nov. 20, 1933, of heart disease.

Andrew Pinkney Brown Davis Okla., Vanderbilt University School of Medicine Nashville Tenn., 1893, member of the Oklahoma State Medical Association, aged 64, died Dec. 13, 1933 in the Wesley Hospital Oklahoma City, of cerebral hemorrhage, following an operation for carcinoma of the intestine.

Milton Edward Gregg, Mottville N. Y., Baltimore Medical College 1896, member of the Medical Society of the State of New York served during the World War, aged 63 died Dec. 13, 1933 in the Auburn City (N. Y.) Hospital, of injuries received when he was struck by an automobile.

William Barker Hills, Upper Montclair, N. J. Harvard University Medical School, Boston, 1874, member of the Massachusetts Medical Society, formerly associate professor of chemistry at his alma mater, aged 83, died, Dec. 24, 1933, of cerebral hemorrhage and arteriosclerosis.

Horace O. Dodge, Denver, Chicago Medical College 1888, at one time professor of therapeutics and physical diagnosis at the University of Colorado School of Medicine Civil War veteran aged 93 died Dec. 29, 1933, in the U. S. Veterans' Hospital, Oteen, N. C., of senility.

William Henry Hancker, Farnhurst, Del., Jefferson Medical College of Philadelphia 1873, member of the Medical Society of Delaware and the American Psychiatric Association, formerly superintendent of the Delaware State Hospital, aged 83, died, Dec. 29, 1933.

Emmet Emerson Newcomer, Washington, D. C., Tulane University of Louisiana School of Medicine New Orleans 1921, member of the Medical Society of the District of Columbia, aged 41 died, Nov. 25, 1933, of coronary thrombosis and hemorrhagic gastro-enteritis.

William Ezra Wetmore, Utica, N. Y. University of the City of New York Medical Department 1889, member of the Medical Society of the State of New York for many years on the staff of St. Elizabeth's Hospital, aged 66, died, Dec. 2, 1933, in New Hartford.

Henry Lonzo Akridge, Brunswick Ga. Atlanta Medical College 1915 member of the Medical Association of Georgia, served during the World War city and county health officer, aged 43 died Dec. 17, 1933, in St. Vincent's Hospital, Jacksonville Fla.

Charles Francis Booth, New York College of Physicians and Surgeons Medical Department of Columbia College New York 1883, member of the Medical Society of the State of New York aged 73 died Dec. 30, 1933, of chronic myocarditis.

Stanley White Barber, Gathersburg, Md., Medical College of Virginia, Richmond, 1913, member of the Medical and Surgical Faculty of Maryland, aged 45, died, Nov. 19, 1933, in the Montgomery County General Hospital, Olney, of acute nephritis

Isaac Pearson Willits ♂ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1880, for many years on the staff of the Germantown Dispensary and Hospital, aged 73, died, Dec. 11, 1933, of coronary thrombosis

Phineas Henry Ingalls ♂ Hartford, Conn., College of Physicians and Surgeons, Medical Department of Columbia College, 1880, for many years on the staff of the Hartford Hospital, aged 77, died Dec. 14, 1933, of heart disease

Leo Halpin, Freeport, N. Y., Cornell University Medical College, New York, 1906, member of the Medical Society of the State of New York, on the staff of the Mercy Hospital, Hempstead, aged 50, died, Dec. 23, 1933, of pneumonia

Nelson William MacMurphy, Belmont, N. H., University of Vermont College of Medicine, Burlington, 1891, member of the New Hampshire Medical Society, aged 75, died, Nov. 23, 1933, of chronic myocarditis and bronchopneumonia

Charles Carlyle Driscoll ♂ Lafayette, Ind., Kentucky School of Medicine, Louisville, 1893, on the staff of the Lafayette Home Hospital, aged 68, died Dec. 19, 1933, in the Methodist Hospital, Indianapolis, of pneumonia

Frank Reid Yarbrough, Auburn, Ala., University of Tennessee Medical Department, Nashville, 1898, member of the Medical Association of the State of Alabama, aged 61, was found dead, Dec. 21, 1933, of heart disease

Samuel Martin Parrish, Raton, N. M., St. Louis University School of Medicine, 1907, member of the New Mexico Medical Society, served during the World War, aged 52, died, Dec. 14, 1933, of pulmonary tuberculosis

Charles Henry Branch, White Cloud, Mich., Kentucky School of Medicine, Louisville, 1905, member of the Michigan State Medical Society, aged 57, died, Dec. 19, 1933, in a hospital at Fremont, of cerebral hemorrhage

Charles Edward White, Fairport, N. Y., University of Michigan Medical School, Ann Arbor, 1896, member of the Medical Society of the State of New York, aged 62, died, Nov. 23, 1933, of cerebral hemorrhage

Elliott Lawson Baker, Jr. ♂ Columbus, Ga., University of Georgia Medical Department, Augusta, 1931, aged 33, died, Dec. 4, 1933, in the Georgia Baptist Hospital, Atlanta, of cerebral hemorrhage and hypertension

Hugh McCallum Thiebaud, Vevay, Ind., University of Louisville (Ky.) School of Medicine, 1895, member of the Indiana State Medical Association, aged 73, died, Dec. 18, 1933, of carcinoma of the mouth

Albert Henry McIntire, Springfield, Ohio, Starling Medical College, Columbus, 1904, member of the Ohio State Medical Association, aged 63, died, Dec. 21, 1933, of dilatation of the heart and chronic nephritis

Henry Barker W. Carmichael, Montreal, Que., Canada, McGill University Faculty of Medicine, Montreal, 1892, L.R.C.P., Edinburgh, Scotland, 1892, aged 66, died in December, 1933, at Bournemouth, England

Harry Horace Dilley ♂ Des Moines, Iowa, Rush Medical College, Chicago, 1917, served during the World War on the staff of the Iowa Methodist Hospital, aged 41, died, in December, 1933, of uremia

Emory Willis Peery, West Palm Beach, Fla., University of Maryland School of Medicine, Baltimore, 1891, member of the Florida Medical Association, aged 67, died, Dec. 4, 1933, of cerebral arteriosclerosis

Joseph Albert Charlebois, Ottawa, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1908, on the staff of the Ottawa General Hospital, aged 49, died Nov. 20, 1933, of coronary thrombosis

Richard Joseph O'Connell, New York, Bellevue Hospital Medical College, New York, 1879, member of the Medical Society of the State of New York, aged 77, died Dec. 19, 1933, of pneumonia

William Rufus Hardin ♂ Louisiana, Mo., Washington University School of Medicine, St. Louis, 1899, aged 58, died Dec. 11, 1933, in the Pike County Hospital, of asthma and chronic myocarditis

Frank Webb Parks, Brinson, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912, member of the Medical Association of Georgia, aged 50, died, Dec. 16, 1933, of heart disease

William Alexander Morrison ♂ Boston, Harvard University Medical School, Boston, 1889, aged 77, died, Dec. 19, 1933, in the Boston City Hospital, of uremia and arteriosclerotic heart disease

Joseph Hart, Dudley, Pa., Jefferson Medical College of Philadelphia, 1889, formerly member of the state legislature of Maryland, aged 72, died, Dec. 18, 1933, of cerebral hemorrhage

Emory H. Morrow, Altoona, Pa., Homeopathic Hospital College, Cleveland, 1883, member of the Medical Society of the State of Pennsylvania, aged 75, died, Dec. 19, 1933, of pneumonia

Thomas Francis Dunn, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1902, aged 56, died Dec. 24, 1933, in the Lankenau Hospital, of injuries received in a fall

Austin Trafton Brant ♂ Boston, Harvard University Medical School, Boston, 1907, fellow of the American College of Surgeons, aged 52, died, Dec. 15, 1933, of cardiovascular disease

James A. Hunter, Fairfax, Mo., Bellevue Hospital Medical College, New York, 1881, member of the Missouri State Medical Association, aged 83, died, Nov. 28, 1933, of acute hepatitis

Sigmond Rosenthal, Aberdeen, S. D., Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1896, aged 71, died, Dec. 15, 1933, of myocarditis

William S. Booze, Annapolis, Md., College of Physicians and Surgeons, Baltimore, 1879, aged 70, died Dec. 6, 1933, in the Homeopathic Hospital, Wilmington, Del., of heart disease

Louis Francois Molleur, Dillon, Mont., Victoria University Medical Department, Coburg, Ont., Canada, 1890, aged 68, was found dead, Dec. 9, 1933, of a self-inflicted bullet wound

John Delbert Nichols ♂ Mooseheart, Ill., Medical College of Indiana, Indianapolis, 1893, medical director of the Mooseheart Hospital, aged 63, died, January 3, of pneumonia

Joseph Alexander Packer ♂ Alexandria, La., Memphis (Tenn.) Hospital Medical College, 1904, on the staff of the Baptist Hospital, aged 54, died, Dec. 2, 1933, of heart disease

Vernon Robins ♂ Louisville, Ky., University of Louisville School of Medicine, 1894, city chemist, aged 61, died, January 1, of pulmonary tuberculosis and arteriosclerosis

George Clinton Blades, Baltimore, Maryland Medical College, Baltimore, 1900, formerly coroner, aged 61, died, Dec. 29, 1933, of diabetes mellitus and myocarditis

Egbert G. Appleton, Beaver Dam, Wis., Hahnemann Medical College and Hospital, Chicago, 1902, aged 57, died, Dec. 16, 1933, in the General Hospital, Madison

Edwin G. Kyte, Detroit, Indiana University School of Medicine, Indianapolis, 1909, served during the World War, aged 48, died, Dec. 23, 1933, of heart disease

Thomas Green Dunlap ♂ Atlantic City, N. J., University of Louisville (Ky.) School of Medicine, 1898, aged 57, died, Dec. 15, 1933, of acute coronary occlusion

George Washington McKinnon ♂ Arcata, Calif., McGill University Faculty of Medicine, Montreal, 1888, aged 72, died, Nov. 21, 1933, of pernicious anemia

Peter L. Gillespie, Wymore, Neb., John A. Creighton Medical College, Omaha, 1901, aged 58, died, Dec. 17, 1933, in Lincoln, of Alzheimer's disease

George Milton Dorris, Bolivar, Tenn., Vanderbilt University School of Medicine, Nashville, 1880, aged 79, died, Dec. 17, 1933, of heart disease

Isaac Park Park, Revere, Mass., Medical School of Maine, Portland, 1892, aged 66, died, Nov. 26, 1933, of cerebral hemorrhage and arteriosclerosis

Albert Ernest Grant ♂ Durham, N. H., Dartmouth Medical School, Hanover, 1897, aged 60, died Dec. 8, 1933, of cerebral hemorrhage

Augustus Herman Keller, Philadelphia, Jefferson Medical College of Philadelphia, 1896, aged 66, died Dec. 25, 1933, of pneumonia

William B. Buchanan, Chicago, Jenner Medical College, Chicago, 1908, aged 55, died, Sept. 9, 1933, of heart disease

Thomas Wright Watson, Long Beach, Calif., Detroit College of Medicine, 1896, aged 62, died, Nov. 7, 1933

Bureau of Investigation

TWO MORE QUESTIONNAIRES

The Beacon Bureau of Research and the Commodity Research Bureau

In this department of *THE JOURNAL* for December 30 the questionnaire nuisance was again discussed. Since that article was prepared two more questionnaires have been brought to the attention of the Bureau of Investigation. One comes from the 'Beacon Bureau of Research' Post Office Box 149 Boston, Mass. As has been previously said the use of some high-sounding name such as Modern Research Society, National Research Bureau, Medical Research Bureau, etc. etc. is a common method by which advertising agencies or commercial concerns or those employed by one or both approach physicians in an attempt to get an expression of expert opinion at the cost of a postage stamp.

The letter from the Beacon Bureau of Research of Boston is frankly mimeographed. Not even the name of the physician who receives it heads the letter. The letter is signed—"with a rubber stamp—John D. Burdett who is described as Supervisor." The Beacon Bureau of Research states that "An able Boston dermatologist frankly told a client of ours that he knew little about the uses of soap and water or their effect on the skin and on public health." Because of this alleged ignorance on the part of physicians in general and dermatologists in particular, the Beacon Bureau of Research was submitting to physicians a 'few questions' that it would like to have answered, and that when these answers had been compiled the results would "later be reported by our client to the profession." Some of the questions that the doctors were asked to answer were:

'Is your knowledge of soaps based on scientific data concerning individual brands, or merely upon your experience with various kinds of soap?' (Please check.) Scientific Data _____ Experience _____

"When you suggest frequent daily hand washings what reasons primarily do you give _____

"When you are asked about soaps, what brands do you suggest for the following uses by healthy normal people _____

Face _____ Shampoo _____

Hands _____ Infants _____

Bath _____

"Do you favor the use of soap and water for any abnormal skin or scalp conditions and how frequently do you have occasion to recommend such treatment? _____ For what condition? _____ What soaps do you suggest for these conditions? _____ Frequency _____

"What soap do you have in use in your office at the present time? _____

From the character of the questions it was fairly obvious that the Beacon Bureau of Research was either a fancy name for some advertising agency that was working up data for some concern that sold soap or was a name assumed for the purposes of the questionnaire by a soap manufacturer. As Sherlock Holmes would say "Elemental, my dear Watson. Investigation indicates that the Beacon Bureau of Research is a fancy name used by a soap manufacturer!"

About the same time that physicians were receiving letters from the Beacon Bureau of Research on soap some physicians wives were getting a questionnaire from another 'research outfit' known as the Commodity Research Bureau operated from the eighth floor of 305 East 45th Street New York City. These letters were sent to the presidents of certain women's clubs. A physician in Texas sent us one of the letters and also one of the several postcards that came with each letter. The physician wrote:

"I am enclosing a letter and card sent my wife as president of a club. This club is composed of mature women with old-fashioned ideas of what is nice. The impudence of some of these people who wish to work a racket like the one proposed is beyond understanding. I suppose that there are presidents of some clubs who will give free service by using the club hours to get women to sign up the cards. My wife was sent about

twenty cards. I rescued one and the letter from the waste basket to send you. Who is the Commodity Research Bureau?"

The letter sent out on the stationery of the Commodity Research Bureau was signed "James W. Blackburn." Mr. Blackburn made a personal appeal to the presidents of the women's clubs in his opening paragraph, which read:

"Will you do me a favor? I have just graduated from Leland and I'm trying to make good at my first job. I've been asked to distribute the enclosed cards among club women and get them to answer three simple questions. The success of my job depends on the number of cards I get filled in during the next two weeks."

The cards that Mr. Blackburn enclosed and which were to be returned to Mr. Blackburn, propounded the following questions:

1. What cigarette do you smoke?
2. How long have you been smoking this brand?
3. What cigarette (if any) did you smoke before?

One can visualize the reaction of many women to questions of this sort. The crudity of sending such questions indiscriminately to women throughout the country might be explained by the fact admitted by Mr. Blackburn that he is just out of college and working at his first job. It was not, however, Mr. Blackburn who was sending out these letters from the eighth floor of 305 East 45th Street. The entire eighth floor of that address is occupied by an advertising agency, Lord & Thomas and Logan Inc. whose experience in the advertising world one might suppose would have prevented them from making a *faux pas* of this kind. In any case one wonders whether it has not yet dawned on the better type of advertising agencies and the more intelligent manufacturers that the questionnaire method of working up data for advertising purposes is an impertinence and a nuisance. The very fact that most of the questionnaires that come out are sent in the name of some concern that has no existence except on paper and are carefully calculated to keep from the recipient of the questionnaire the name of the concern that is back of it would indicate that it is recognized that there is no legitimate excuse for imposing on the public either professional or lay, in this manner.

Correspondence

"SPINAL ANESTHESIA IN HYPERTENSION"

To the Editor.—My preliminary note on the use of spinal anesthesia in hypertension (*THE JOURNAL* Oct. 28 1933 p. 1410) has apparently served to arouse considerable interest in this subject if I may judge from the number of favorable communications that have been received. The objection of Dr. L. J. Bragman (*THE JOURNAL* Dec. 16 1933 p. 1985) to this method on the 'theory that lowering blood pressure in persons with hypertension and arteriosclerosis may bring on attacks of hemiplegia and aphasia' is perhaps more academic than real.

In my own series of 3,000 spinal anesthetic records, I did not encounter a single instance of hemiplegia, aphasia or convulsions. Dr. Lazarus (Lazarus, J. A., Pick, C. J., and Rosenthal, A. A. *Tropacaine Hydrochloride in Spinal Anesthesia*, *Ann Surg* 97:757 [May] 1933) tells me that in his series of 2,500 cases he has never seen this particular type of complication. Dr. H. C. Falk (Death from Spinal Anesthesia, *Am J Surg* 9:461 [March] 1931), in his series of 4,000 spinal anesthetics has written to tell me that he likewise has never seen hemiplegia, aphasia or convulsions following such drops in blood pressure. Dr. P. N. Charbonnet (*Spinal Anesthesia in a Series of 300 Abdominal and Pelvic Operations*, *Am J Obst & Gynec* September 1933) writes that his use of spinal anesthesia in more than 700 cases has never resulted in the complications mentioned. Dr. Louis Abelson in a series of 3,000 cases and Dr. Charles J. Pick with 3,200

have both volunteered the information to me that they likewise have never seen this particular complication.

In the brief period since Dr Bragman's letter was published there has been accumulated altogether a combined series of more than 22,000 spinal anesthetic cases in which no single instance of hemiplegia, aphasia or convulsions was recorded.

This communication, however, is not written with the intention of minimizing the theoretical complications that may follow the sudden lowering of the blood pressure in persons presenting the alarming symptoms associated with the prodromal phases of apoplexy. From a purely statistical point of view the complications suggested by Dr Bragman have apparently not developed. For this reason the method of sudden lowering of blood pressure by spinal anesthesia is still the simplest and most expeditious procedure in the treatment of those cases previously described in my original communication.

ALBERT S. HYMAN, M.D., New York

Director, Witham Foundation for the Study
and Prevention of Heart Disease

To the Editor—I have read Dr Louis J. Bragman's communication on spinal anesthesia in hypertension in *THE JOURNAL*, Dec 16, 1933, page 1985. Your readers will be interested in a short note appearing in the December issue of the *American Journal of Surgery* wherein I discuss the control of inaccessible hemorrhage by blood sequestration in the lower extremities through high elastic ligation of the thighs. There is an immediate and great reduction of systemic blood pressure, and the application of this principle in cerebral hemorrhage is suggested. The method is extremely simple and is apparently without danger.

In a communication from Dr George W. Reese on the same page as Dr Bragman's note, vomiting in spinal anesthesia is mentioned, an accident which I too have observed. Surely, vomiting is not conducive to the arrest of cerebral hemorrhage.

HOWARD LILIENTHAL, M.D., New York

LEUKEMIC INFILTRATIONS OF THE CENTRAL NERVOUS SYSTEM

To the Editor—In his discussion of the article by Garvey and Lawrence on facial diplegia in lymphatic leukemia (*THE JOURNAL*, Dec 16 1933), Dr R. H. Jaffe said: "While in malignant tumors metastases develop from the primary tumor by the implantation of cells derived from the primary tumor, the leukemic infiltrations develop locally from the undifferentiated mesenchyma."

Many pathologists accept the fact that the local undifferentiated cells of the mesenchyma (mesodermal tissue) throughout the body participate in the provision of the leukemic elements. An example of the aboriginal proliferation of cells in leukemia is furnished by the observation that in the subcutaneous leukemic nodules the cells are not imported but produced locally. However, lymphomas found in the brain are essentially formed by immigrated cells. In my article on leukemia and the central nervous system (*Arch Path* 2:23 [Jul] 1926) to which Garvey and Lawrence made reference, I said: "The occurrence of lymphomas in tissues like the brain where lymphoid cells are normally absent, is due to the passage of the vascular wall by lymphoid cells with the ultimate formation of large nodules, which occasionally grow as autochthonous units."

If one is to accept the notion that lymphocytes like macrophages originate from undifferentiated perivascular cells, one must also appreciate that in the brain their number is not sufficient alone to form large lymphomas, illustrations of which were given in figures 4, 5 and 6 of my article. Moreover a

study of the vessels reveals that their lumens as well as the Virchow Robin spaces, are crowded "to capacity" with leukemic cells. Ruptured vessels resulting in wide hemorrhages, and diffusion of white cells are also found.

The accumulation of leukemic cells in the brain is defined as "colonization" by immigrating cells and differs from the implantation of the cells in metastases of malignant diseases.

B. M. FRIED, M.D., New York

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

TREATMENT OF CHANCROIDS

To the Editor—Will you let me know the latest and best treatment for chancroids?

H. B. TAYLOR, M.D. Anking China

ANSWER—The best treatment of chancroids consists in prophylaxis. The use of plenty of soap and water following exposure will ordinarily preclude a case of chancroids. Once they have been established, and provided a true diagnosis has been made by the microscope, early treatment is recommended. An early case can occasionally be abated by the local application to the individual lesions of pure phenol followed by alcohol. In case bubo formation has already begun, this form of therapy is contraindicated, as it predisposes to suppuration of the bubo. Naturally if this form of therapy is used, all lesions must be carefully treated, none being overlooked.

Other approved local remedies are hot astringent soaks of potassium permanganate or of boric acid 1:3,000, three or four times a day. As the Ducey bacillus grows best when shut off from air, it is well to use no bandages. The lesions should be kept exposed and dry heat should be employed in the form of an electric light inside a tent. Sprinkling the lesions with powdered iodoform is also helpful. If the patient has a long foreskin and a complicating balanitis, circumcision under hospital conditions is helpful and will lessen sick days enormously (Rauschkolb, I. E. Circumcision *Arch Dermat & Syph* 21:251 [Feb] 1930). The skin edges should be approximated with clips as sutures tear out. One should not hesitate to cut right through the chancroidal ulcers. With careful hospital technique the results are excellent. Following operation asepsis and loose sterile gauze flaps over the penis may be used. No bandages should be applied. The hot applications and dry heat and iodoform should also be continued.

If the patient has developed a bubo, rest in bed and local heat are essential. If the patient is seen just at the time when the bubo has begun to soften the following injection technic is satisfactory (Miskjian, H. G. Chancroidal Buboes *THE JOURNAL*, Oct 30 1926, p. 1436; Cole, H. N. Venereal Disease Information 10:1, 1929). In performing the technic, one should wait until fluctuation is noted, with a certain amount of softening over the lymph nodes. A slight nick 1 cm in length is then made with a sharp knife near the base of the surface slanting down toward the thigh. Under gentle expression the pus is allowed to run out as much as it will. Following this a compression bandage is applied, plenty of gauze being used immediately over the lymph node in order to get heavy compression for a period of twenty-four hours. During this time the patient is supposed to lie flat in bed with the legs unflexed, in order to get as much pressure locally as is possible. The bandage is then removed, the pus in the cavity is completely evacuated by pressure with the fingers, and under aseptic precautions 1 or 2 cc of Mercier's solution (iodoform, guaiacol, eucalyptol and 95 per cent alcohol, each 10; balsam of Peru 30; ether, 100) is injected into the cavity of the lymph node. A record syringe is used for this purpose; the nozzle of the syringe without a needle being simply forced into the small aperture that was made twenty-four hours before the elbow of the syringe being pressed up firmly against the skin in order to prevent the fluid from escaping. This fluid, which causes severe burning for a few seconds, is allowed to remain in the cavity of the lymph node for one minute. It balloons out the cavity in such a way that all the interstices and pockets receive a certain amount of the preparation which is antiseptic, astringent and reducing in its properties. The hope is that

the cavity will be entirely sterilized from this contact with the fluid. The fluid is then allowed to run out from the opening and is gently expressed to get out all the remaining Menciére solution. After this another heavy compression bandage is applied and allowed to remain in place for forty-eight hours. The patient is again advised that he must not flex his legs but should keep them extended in order to have heavy compression over the area. At the time the bandage is removed one may note that some clear serum runs from the opening of the lymph node cavity. This simply indicates an irritation type of fluid and is of no moment. The fluid is pressed out and another compression bandage is applied and allowed to stay on for another twenty-four hours. At the end of this time, if the cavity still continues to discharge pus another injection of Menciére's solution will have to be made according to the technique described.

In a large proportion of the cases if the technique is properly carried out one treatment will be sufficient to cure the bubo. In certain of them if pus is noted instead of serum one or two more injections may be necessary. The injection should not be repeated in less than three days. With this injection technique, hospital bed days have been enormously lessened and likewise sick days for the patient.

In European countries *Emelcos vaccine* (*Ducroix bacillus*) is used with great success. Government regulations prevent the entrance of this valuable agent into the United States. It is of special value when buboes have developed.

In treating a chancroidal infection the physician should not lose sight of the fact that his patient may have a double infection of chancroids and complicating syphilis. A weekly Wassermann test should be done in such a case until all chance has passed of syphilis developing.

AMEBIC DYSENTERY IN CHILD

To the Editor—A boy aged 2½ years for the past four months has had attacks of vomiting and slight diarrhea with low grade fever. Examination reveals the presence of *Endamoeba histolytica* in the stools. There is no blood but some mucus is seen at times. In between these attacks he is quite well and the stools are rather firm and normal in appearance. His appetite has not been up to usual and his usual vigor has been somewhat reduced since the beginning of this disorder. The child's mother is suffering from an amebic infection. What would be the treatment in a child of this age. Please include dietary advice as well as medicinal. Please omit name.

M. D. California

ANSWER—It is obvious that the most important point in the treatment of this child would consist in preventing reinfection from the mother, who is also suffering from the disease or from any other member of the family who might be infected. It might be necessary to separate the child from the mother and treat either or both of them in a hospital.

There is some difference of opinion as to the selection of the proper drug to be used since a number of remedies have been recommended and medical writers are not all agreed as to their relative efficiency.

The emetine preparations have been advised though their use is not without considerable danger. Emetine is but slowly excreted, so that cumulative poisoning may readily occur on repeated use. It is particularly toxic to the heart muscle. If used at all, its dosage should be based on body weight and should not exceed 1 milligram ($\frac{1}{160}$ grain) per kilogram of body weight. It should be given intramuscularly one injection daily in the following doses: 0.065 Gm (1 grain) for an adult, 0.02 Gm ($\frac{1}{4}$ grain) for children 8 years of age, and 0.01 Gm ($\frac{1}{80}$ grain) a day for younger children. This dosage should be continued for six days and then half of the doses mentioned should be continued for the following six days. This should constitute a course of emetine treatment, following which there should be a rest period of ten days or more. Emetine bismuth iodide may be given in keratin coated pills or capsules, by mouth. The dose for a child is from 0.016 to 0.065 Gm ($\frac{1}{4}$ to 1 grain) twice daily. This preparation should not be given at the same time that emetine injections are used. Emetine bismuth iodide is difficult and unpleasant for the patient to take and may cause intense emesis. Like the other emetine preparations, it should not be given over an extended time.

Acetarsonone may be given in 0.1 Gm (1½ grain) doses once daily for about eight or ten days followed by an interval during which the drug is omitted for eight or ten days. If fever, gastro-intestinal symptoms or skin eruption occurs its administration should be stopped.

Carbarsone, another arsenical has been recommended because of its low toxicity. Carbarsone has been tested by a number of authorities and is thought to be effective in amebic dysentery. A child of 2½ years may be given 0.065 Gm (1 grain) once or twice daily for a period of ten or twelve days.

There are a number of drugs related to iodohydroxyquinoline among which may be mentioned chumofon which is marketed under the names *maivodin* and *vitren*. Of this group *iodohydroxyquinoline* or *vioform* has been preferred by a number of writers. The dose of *vioform* for an adult is 0.25 Gm (4 grains) once or twice daily. For children this dose should be reduced according to age.

CROSS AGGLUTINATION OF BLOOD—ASPIRATION OF SPINAL FLUID

To the Editor—1. What is the explanation of cross agglutination occurring within the same blood group? Recently in attempting to find a donor for a blood transfusion it was practically impossible for me to find suitable blood within the same group as there was always agglutination when the serum of the recipient was typed directly with the cells of the possible donor. Is this common? Does marked anemia on the part of the recipient have any influence? Would it be safe to use such bloods although only a small amount of agglutination occurred? 2. What is the explanation for the fact that in using spinal anesthesia there is frequently difficulty in aspirating the spinal fluid into a syringe although the spinal fluid drops out of the needle freely? I have frequently gotten into this difficulty and although I was sure that the needle was in the subarachnoid space as evidenced by the flow of spinal fluid the flow of spinal fluid stopped as soon as a little suction was applied by the syringe. Isn't this probably due to the aspiration of some tissue into the eye of the needle?

FRANK R. GUIDO, M.D., Visalia, Calif.

ANSWER—1. Cross agglutination within the same blood group may be due to the following factors:

(a) Subgroups within any one of the four blood groups. e. g. group A has been reported to contain several subgroups. If the recipient is in group A and the donor in a subgroup of group A, cross agglutination might take place comparable to that occurring between two distinct blood groups.

(b) Auto agglutination. Rarely the recipient's serum may agglutinate his own erythrocytes as well as those of all donors. Auto agglutinins are demonstrable at temperatures lower than the temperature of the body when they are absorbed from the serum and attached to the red cells. The auto agglutinins can be freed from the erythrocytes by washing and resuspending in physiologic solution of sodium chloride at 37°C.

(c) Rouleau formation (pseudo agglutination). A heavy rouleau formation may be mistaken for true clumping. This error can be avoided by observing microscopically the process of rouleau formation. Abnormal temperatures and drafts encourage rouleau formation. Dr. A. S. Wiener discussed rouleau formation in *THE JOURNAL*, Oct. 21, 1933, page 1317.

(d) Sensitization. One transfusion of blood from a given donor may occasionally sensitize the patient to this blood as demonstrated by the clumping of the donor's red cells by the serum of the recipient.

Cross agglutination within the same blood group is not common.

Marked anemia, blood dyscrasias, severe toxemia and sepsis on the part of the recipient apparently increase the occurrence of cross agglutination within the same blood group.

A donor's blood should not be transfused when there is agglutination in the mixture of the recipient's serum and the donor's corpuscles.

2. Placing the syringe on the needle that has been inserted in the subarachnoid space may displace the needle either pulling it out of the space or pushing the needle through the space.

In these cases the opening of the needle is in close proximity to the membrane and while spinal fluid may come out in drops aspiration produces a plugging of the lumen by drawing the membrane to it. This occurs particularly when the needle is inserted at an angle and not perpendicular to the canal, and its opening lies either just beyond the dura or close to the dura all the way across the canal.

Cerebrospinal fluid circulates through the lumbar subarachnoid space at a definite rate which can be increased only by an increase of pressure within the subarachnoid space (such as by pressure on the jugular vein). Removing fluid from the lumbar subarachnoid space by aspiration does not serve to increase the rate of flow of fluid into this space but simply serves to create an area of negative pressure within it. This results in an obliteration of the subarachnoid space by collapse of the subarachnoid and dural tissue (it is to be kept in mind that the dura in the lumbar region is much less adherent to the bony wall than it is in the thoracic and cervical regions). The result of this collapse is to shut off the flow of cerebrospinal fluid from the subarachnoid spaces above, both by virtue of block of the subarachnoid space and by virtue of clogging of the end of the needle by tissue. Thus it is not possible to aspirate cerebrospinal fluid from the subarachnoid space at a

rate faster than that at which it flows of its own accord. And by virtue of the block above, no fluid may be obtained at all. An attempt to aspirate cerebrospinal fluid may cause trauma to the dura and subarachnoid tissue and headache. Aspiration is therefore undesirable.

TOXICITY OF NAPHTHALENE

To the Editor—I have a patient who in the course of his employment comes in contact with naphthalene crystals and gases. Recently while performing an experiment he inhaled the fumes from a mixture of cement asbestos fiber, silica and naphthalene which had been heated to 335 F. That night he had a typical acute asthmatic attack, which lasted for forty-eight hours. After a week's rest he returned to work and several days later he had another asthmatic attack. The patient thinks that the naphthalene gas is the cause of his asthma. Could I determine his sensitivity to naphthalene by means of the patch test? I would appreciate any information or references on the hazards of naphthalene. Please omit name.

M D, New Jersey

ANSWER—Naphthalene has been mentioned as a so-called industrial poison by numerous investigators and writers. As far back as 1884, Evers (*Beil klin Wchenschr* 42 593) reported a case of eczema resulting from contact with the crystals used as an insecticide. Since then many similar cases have been reported in dermatologic literature, the sensitive individuals exhibiting varied symptoms, from mild headaches and loss of appetite to severe intoxication with vomiting, diarrhea and prostration, as well as the typical lesions of an acute eczema.

Peterson, Haines and Webster (*Legal Medicine and Toxicology* 3 694) say: "It is moderately volatile at ordinary temperature, and poisoning has resulted from inhalation of its vapors, thus persons sleeping under bedclothes dusted with naphthalene as a moth powder have suffered from loss of appetite, headache and eczema."

In the individual case under investigation, sensitivity could be tested by means of the patch test, which has been used successfully by other investigators. However, the investigation should not stop there. A roentgenogram of the patient's lungs is of primary importance, because of the possibility of a silicosis or an asbestosis being present. Cement, asbestos and silica have all been known as causes of respiratory disorders, and many papers have been written on the subject of pneumoconiosis from each of these substances. It is well known that this condition may be present for years before any symptoms appear, and it is not an unusual finding in the roentgenograms of lungs of older asthmatic persons. The knowledge of this fact is especially important in the treatment and prognosis of the case.

It must be borne in mind, too, that this patient may be suffering from a true bronchial asthma, and the onset of his initial attack, following the inhalation of fumes might be merely coincidental. Many asthmatic attacks may be precipitated or made worse by the inhalation of gas or fumes when the actual cause is something entirely different. In this case the routine scratch and intradermal testing with proteins should be carried out, as well as a differential blood count for the presence of an eosinophilia. A history in the family of hay fever, asthma, urticaria or migraine, or the presence of some other allergic manifestation in the patient himself, would be a still further aid in the diagnosis.

VACCINATION AND BONE TUBERCULOSIS

To the Editor—Is active tuberculosis of the bone in a child a contra-indication to vaccination against smallpox? May such vaccination be expected to cause an exacerbation in quiescent bone tuberculosis? Will you state a few references covering the question?

HENRY McCUSKER, M D, Providence R I

ANSWER—It is difficult to formulate rules in such circumstances. There is no doubt that vaccination in an active and even in latent bone tuberculosis will put the defensive mechanism of the body to the test. Although there are no specific references in the literature to an exacerbation of tuberculous bone lesions, H A Gins (*Zentralbl f Bakt* 127 77 [Dec 30, part 1] 1932) reported three cases of tuberculous meningitis in apparently latent childhood tuberculosis following vaccination. There is no reason why the same could not happen in bone tuberculosis. This is particularly true in children.

Especially could such a result be possible in the occasional patient having bone lesions as a result of vaccinia (Brinkmann, *E Ztschr f orthop Chir* 57 208 1932. Solito, M. *Quadrant radiol* 3 73, 1932. Smith, R M. *New York M J* 108 618 1918).

But in adult disease there is apparently little risk, since both Wiese (*Deutsche med Wchenschr* 45 580 [May 22] 1919) and Mark (*THE JOURNAL*, March 8, 1919, p 704) found no

untoward effect in more than 200 cases each of pulmonary tuberculosis.

Regarding specific examples of tuberculous bone lesions and vaccinia, the literature on the subject is scanty. As a working rule it might be wise to refrain from vaccination only while the disease is early or in the stage of active evolution, and not then when the child has been definitely exposed. Following definite exposure, it is better to take a chance on mild vaccinia than on virulent smallpox, irrespective of the outcome.

EXPOSURE GUIDE FOR ROENTGENOGRAPHING HEART AND LUNGS

To the Editor—I should like an exposure guide for the heart and for the lungs in infants and children up to 16 years. The manufacturer of the x-ray machine I use recommends for adult chests (lungs) a distance of 40 inches 30 milliamperes, a kilovolt peak of from 65 to 90 depending on the depth of the chest. For a depth of 7 inches a kilovolt peak of 65 and for a depth of 12 inches a kilovolt peak of 90 and an exposure time of one fourth second. For hearts the distance is increased to 72 inches and the time to one second. These figures are for flat films only made with cassettes containing intensifying screens. If published omit name and town.

M D Ohio

ANSWER—The matter of x-ray technic in the examination of heart and lungs is still an open question. At the present time various technics are being used, ranging from 30 to 400 milliamperes, in some instances 1,000 milliamperes is being used.

If a high milliamperage is used a broad focus tube is necessary, in order to withstand the large amount of energy used. It also follows that if a broad focal spot is used less detail can be obtained, and this can be compensated for only by increasing the target film distance. Therefore, if high milliamperage is used, from 400 to 1,000 milliamperes, the tube distance would of necessity be at least 72 inches. The kilovoltage, when one is using high milliamperage, ranges between 45 and 75 kilovolts, according to the thickness of the patient. The time in most instances is around one-twentieth second.

If 30 milliamperes is used, the target film distance is in the neighborhood of 36 inches. The focal spot of a 30 milliamperage tube is small and therefore gives rather sharp detail. Usually the kilovoltage is from 65 to 85, and the time ranges between one-fourth and one-half second. The 100 milliamperage technic is the most popular at this time, a 6 kilowatt tube having a focal spot from 2.5 to 3 mm being used. The usual target film distance is 48 inches, the kilovoltage from 65 to 85 and the exposure time usually from one-tenth to one-twentieth second. It is not necessary to use an exposure faster than one-twentieth second, as almost all movement can be obviated by an exposure of one-twentieth second. Satisfactory films can be obtained with the last mentioned technic.

AREA OF TELEROENTGENOGRAMS

To the Editor—Will you please advise me where I may secure a reliable formula for calculating the surface area of six foot teleroentgenograms. Also I should like to have the adult tables for calculating heart surface areas according to Eyster.

P W FLAGGE M D, High Point, N C

ANSWER—P C Hodges has shown (*Am J Roentgenol* 11 466 [May] 1924) that when a subject sits erect and breathes quietly for examination either by teleroentgenography or orthodiagraphy, individual variations in heart size are less than 10 per cent. It follows that normal tables based on orthodiagraphic cardiac area measurement may be used to compute the normal frontal plane area for comparison either with teleroentgenograms or with orthodiagrams. The actual silhouette areas obtained from teleroentgenograms must be subjected to correction for distortion. In general, 10 per cent for area and 5 per cent for greatest transverse diameter will serve for films made at a six foot target film distance. The exact distortion factor for any particular setup may be computed easily by substituting the proper values in the proportion $A_h A_r T_h T_r$, in which A_h equals the unknown or actual heart size, A_r equals the cardiac area of the film, T_h equals the distance from the tube target to the central plane of the heart, and T_r equals the distance between the tube target and the film. A_h and T_r are readily measurable. T_h may be computed by measuring the distance between the plane of the film in the cassette changer and a point 8 cm in front of the cassette changer (which point will represent the average position of the heart in the chest) and subtracting this distance from the value for T_r .

Van Zwaluwenberg and Warren (*Arch Int Med* 7 137 [Feb] 1911) gave the following formula as a satisfactory substitute for the planimetric measurement of the cardiac area taken from the film: one fourth of 3.1416 times the product of

the long axis and the short axis. Although this is fairly satisfactory, the actual measurement of the cardiac silhouette with a planimeter designed to read in square centimeters is much more satisfactory. Instruments of this sort can be purchased from firms dealing in engineering instruments. This instrument is extremely easy to operate.

A formula for predicting the normal heart surface area for adults appeared in an article by Hodges and Eyster (*Am J Roentgenol* 12 252 [Sept] 1924). This article contains a convenient set of tables for ready reference. These tables were republished together with similar tables for estimation of the transverse diameter by Hodges and Eyster (*Irish Int Med* 37 707 [May] 1926).

CIRCUMCISIONS UNDER LOCAL ANESTHESIA

To the Editor—I do many circumcisions. Occasionally I have a case in which the organ swells on the dorsum the skin turns black and leathery blebs form and eventually there is some sloughing of the skin. It is not like an infection—there is no pus—there apparently being just death of the tissue from having its nutrition cut off. I should like some light on the subject. My first case was in a paralytic and I attributed it to devitalized tissues. I used 0.5 per cent of procaine hydrochloride with epinephrine. Then I had two or three cases in close succession in which I used nupercaine 1:1000. I changed back to procaine without the epinephrine and in the course of time I had two more such cases. Recently I did one under general anesthesia thinking possibly that the trouble in the previous case was due to local anesthesia but the same condition developed. In the last three cases I have avoided the slough by prompt and active measures—using the heat lamp and antiphlogistic treatment constantly in alteration. So far as I can recall in each of these cases the dorsal artery was very large and had to be ligated. Is it possible that the dorsal artery had not the usual branches and that when the main artery was severed there was not sufficient blood supply to the area? Understand these are only occasional cases among many. I wonder whether others have had the same experience. Please omit name.

M D Colorado

ANSWER—Necrosis of the skin of the penis following circumcision has been noted by a number of surgeons following the use of local infiltration anesthesia. Braun in his book on local anesthesia called attention to the danger of a slough from using too large amounts of epinephrine.

McWhorter (*Surgical Clinics of Chicago* 4 151 [Feb] 1920) pointed out the danger of a slough in any region having a poor blood supply or end arteries from infiltration anesthesia and that certain drugs were more toxic and slowly absorbed than others, procaine probably being the least toxic.

He advocated the following rules:

- 1 The use of 0.5 per cent procaine hydrochloride with one drop of 1:1000 epinephrine to 15 cc of solution.
- 2 Operating without the use of a constrictor at the base of the penis.
- 3 Injection under little tension and the use of a minimum amount of solution.
- 4 The choice of nerve blocking anesthesia for circumcision in place of the infiltration method.
- 5 Care in preserving the blood vessels from injury by the needle and rigid hemostasis.
- 6 The use of interrupted sutures.
- 7 Careful asepsis and frequent loose postoperative dressings.

Warm moist boric acid solution compresses have been found beneficial.

Almost certainly a strict adherence to the technic and principles outlined will prevent future complications.

DISCONTINUING MILK SECRETION

To the Editor—A woman aged 24, had her second baby about two months ago. She nursed her child for six days only 2 ounces (60 cc) of milk could be pumped out of her breasts on the seventh day post partum. In spite of applications of camphorated oil complete abstinence from drinking and breast binders milk still formed. I recommended theobromine sodiosalicylate (*C. Merck's Jahresbericht* 46 145 1932) to my patient. She took 0.5 Gm five times a day for ten consecutive days, without discontinuing the abstinence from drinking the application of camphorated oil and the wearing of very tight breast binders. The only visible result of the theobromine treatment was a loss of weight of 3 Kg (from 57 Kg to 54 Kg). What would you suggest as the next possible treatment? Please omit name.

M D New York

ANSWER—For a long time potassium iodide has been recommended to diminish the secretion of milk, but the results are inconstant. More satisfactory results have been reported by Wachtel (*Zentralbl f Gynak* 53 987 [April 20] 1929) for the administration of thiothiod, which not only inhibits the secretion of milk but also acts as a diuretic.

Ten years ago Frankl (*Am J Obst & Gynec* 6 399 [Oct] 1923) proved that in animals known to have an ample supply of milk the effective grafting of placental tissue temporarily

prevented the secretion of milk. This is true in spite of the fact that the placental hormones prepare the breast during pregnancy for their secretory function. Stimson (*Am J Obst & Gynec* 4 413 [Oct] 1922) reported a case in which the secretion of milk remained in abeyance until retained pieces of placenta were removed from the uterus, after which the flow of milk was normal. Hence it may be advisable to administer placental extracts in this case to try to suppress the flow of milk.

G Van S and O W Smith (*Am J Physiol* 103 336 [Feb] 1933) showed that large doses of estrogenic substance (in this case, theelin) prevent lactation in rabbits after parturition. It was not always possible to stop lactation once begun particularly if it had continued for some time before treatment was instituted. It appears that the estrogenic factor of the placenta is largely if not entirely responsible for the antilactogenic effect of placental remnants. Whether or not these results are applicable to man is conjectural but in view of the uncertainty as to composition and potency of placental extracts the use of a preparation of known activity would seem preferable. Of course, such use is not without possible dangers.

INFESTATION WITH GIARDIA

To the Editor—Will you kindly let me know the life history of *Giardia lamblia* as I do not find it described in any of the books available and also the latest method for dealing with infestation with this flagellate? Some time ago I received for examination a stool from a patient with acute diarrhea with mucus and blood a child aged 7 months of American parentage. The specimen which was sent in the baby's diaper was nearly dried up when received it was clay colored and showed no mucus but no visible blood. Microscopic examination revealed numerous light brown oval cysts each about 15 microns in length and 10 microns broad with a central axostyle running straight along its axis and two faint nuclei. The diaper had a peculiar odor not unlike that of fresh pork. A fresh specimen specially asked for showed in addition to the cysts a few actively motile *Giardia* organisms which could be easily distinguished by their characteristic shape and the peculiar tumbling movements. This fresh stool also had the odor described and contained red blood corpuscles, dead leukocytes and a large amount of cellular element. The flagellates had evidently just passed into the cystic stage as in every cyst only one straight axostyle could be detected nor it showed any S shaped division or four nuclei. The child was treated with dilute bowels with laxatives of weak gumme and a specimen examined three days subsequently still showed a few *Giardia* cysts but in a disintegrated condition. Three days later no cysts could be detected and the stool did not have the peculiar odor. The child is quite well now. Please omit name.

M D Kodukuru South India

ANSWER—The life cycle of all the *Giardias* is comparatively simple.

Infection can be experimentally acquired by swallowing the flagellate forms but as these are short lived outside the body they are probably of little practical importance. The cysts however can live outside the body for several months provided they are protected from certain adverse conditions, chief among which is drying. After being swallowed, the cysts pass to the small intestine where encystation takes place and two flagellates emerge from each cyst. These reproduce by binary fission and colonize chiefly the duodenum. Some of the flagellates pass down the intestine and if they are not swept out too quickly encyst and undergo one or sometimes several divisions after encystation.

The case report strongly suggests an acute *Giardia* diarrhea. Most investigators believe that *Giardia* may produce intestinal disorder, but so far it has been impossible to get unequivocal evidence of its pathogenicity and to eliminate possible concomitant factors. There is no good evidence that the parasite ever produces ulceration or penetrates the intestinal mucosa. It is generally held that although the infection may give rise to a marked diarrhea with quantities of mucus, no blood occurs in the stools. In any case most infections are not associated with any observable symptoms.

SENSITIVITY TO HOUSE DUST

To the Editor—When a patient with symptoms of allergy shows a marked hypersensitivity by skin tests to house dust, how may a preparation from house dust be made suitable for hypodermic injection to increase the subject's resistance? What would be the initial dose?

HUBERT M. ENGLISH M D, Cary Ind

ANSWER—The usual method of preparation of house dust extract for treatment purposes is as follows. The dust is collected, preferably with a vacuum cleaner, from the rug-upholstered furniture and mattresses. A weighed amount is covered with ether, to remove the fatty materials and allowed to stand for twenty-four hours. This ether is drained off and fresh ether added. Usually two ether extractions suffice. The residue, after the final draining off of the ether, is spread

on filter paper and allowed to dry. The extracting fluid is then added in a quantity of ten times the weight of the dust. The extracting fluid used ordinarily is Coca's solution which consists of an aqueous solution of 0.5 per cent sodium chloride, 0.4 per cent phenol and 0.25 per cent sodium bicarbonate. After twenty-four hour extraction the material is filtered and the filtrate is sterilized by Berkefeld filtration. Sterility of the solution is assured by making aerobic and anaerobic cultures of the filtered material.

When the extract has been proved sterile it is ready for use. Most patients may begin with a 0.05 cc dose of this extract. In very sensitive individuals this stock dust may have to be diluted ten or a hundred times before it is ready for use.

COLT

To the Editor—Is gout as prevalent as it was formerly? If not why not? Is it still supposed to be due to wine drinking? If so has wine drinking decreased? Please omit name. M D West Virginia

ANSWER—Statistics on the prevalence of gout are probably misleading because of the fact that many cases are not diagnosed and because it is not certain whether the cases of so called irregular gout should really be classified with this disease. The conservative opinion is that in cases which do not present tophi in which urate crystals have been microscopically identified, the diagnosis of gout cannot be definitely established.

The consumption of wine and of alcoholic (especially malt) beverages is supposed to favor the onset of gout and to aggravate the condition when present. However, gout may occur in teetotalers. Prohibition in this country with its coincidental increase in home production and extralegal supply has made the estimation of wine consumption almost impossible. Recent European figures show a declining tendency in wine consumption.

For a discussion of the probable incidence of gout the reader is referred to an article by Joseph H Pratt (*M Clin North America* 8 1685 [May] 1925).

PREPUTIAL INFLAMMATION

To the Editor—Can you tell me of an effective method of treatment for stubborn preputial inflammation? This condition occurred in a man aged 56 and has persisted over three months. The only history obtainable was that of a possible contraction through use of a urinal while in the hospital. The Wassermann reaction is negative. There is no urethral discharge. Retraction of the prepuce is painful. The glans is extremely sensitive. There are scattered raw areas with loss of mucous membrane over the glans and especially around the corona glandis. No deep excavations are noted in the superficial shallow ulcerations. There was a slight mucopurulent discharge. Smears show numerous coarse irregular spirochetes similar to those of Vincent. Cultures as well as smears are negative for the bacillus of Dugrey. The following measures have not been effective: dusting powders, such as cornstarch or cornstarch with calomel and bismuth irrigations with potassium permanganate 1:8000, iodoform powder and the local use of 1 per cent neosphenamine as in Vincent's angina. The last mentioned could not be tolerated and was discontinued after one application on account of the possibility of producing neosphenamine necrosis. Irrigations with plain water containing hydrogen dioxide could be tolerated fairly well. Two per cent aluminum acetate was not tolerated very well. 1:2500 metaphen was tolerated fairly well but does not improve the condition. Treatment on the whole is very annoying and unsatisfactory on account of the extreme sensitivity of the glans. Kindly omit name. M D Michigan

ANSWER—This infection, in all probability, is due to an anaerobic organism.

If the prepuce could be kept behind the glans so that the under surface of the prepuce and glans penis could be exposed to the air, healing might follow. This should be supplemented by the application of solution of hydrogen dioxide. If the prepuce is tight and retraction not possible, circumcision should be carried out.

DIATHERMY AS AID TO PROSTATIC MASSAGE

To the Editor—I would appreciate it if you would answer the following questions: 1 As an adjunct to prostatic massage in the treatment of chronic prostatitis is diathermy of much value? 2 If so where can an apparatus be purchased for home use? 3 What is the price of such an apparatus? Please omit name. M D Iowa

ANSWER—1 Medical diathermy if judiciously administered is a powerful adjunct to the mechanical treatment of prostatitis.

2 The various makes of diathermy apparatus approved of by the Council on Physical Therapy of the American Medical Association are furnished by any reputable surgical instrument house. Diathermic treatments of any kind should be administered only by an experienced operator.

3 The price of a diathermy apparatus varies from \$100 to \$600 according to the number of additional appliances and the magnitude of current to be furnished.

EXTENSIVE HIRSUTISM

To the Editor—Do you know of any treatment given to the mother to reduce the tendency to excessive hairy condition in the child excluding any glandular deficiency in the mother?

A G DAVIS M D Utica, N Y

ANSWER—If glandular deficiency were excluded in the mother there probably would be no tendency to excessive hairy condition in the child. Hirsutism and the various disorders of hair growth and distribution, particularly on the side of excess growth, are due to some glandular disorder, usually pituitary or suprarenal dyscrasias of some sort. Some teratomas of the pineal gland are accompanied by precocious sexual and somatic development which includes overgrowth of hair. Tumors of the suprarenal cortex in children are also accompanied by precocity. Some children showing what are ordinarily thought of as signs of pituitary deficiency exhibit an excessive growth of lanugo like hair. This is most often particularly marked on the distal extremities. There is no way of telling in advance whether a child is likely to exhibit excessive hair growth except when it might have a long line of ancestors who are victims of overgrowth of hair. In this instance the hereditary features would be likely to victimize the child. Even so this tendency is probably based on an endocrine factor. There is nothing that can be done in the way of treatment to the mother to prevent its development in the child.

TREATMENT OF TRACHOMA

To the Editor—I should like to have sent to me a method for the treatment of trachoma in school children. 140 in the grade school and 75 in the high school. It is present in about 75 per cent of the pupils. Copper citrate 5 per cent has been tried for only a short interval and many are using mild silver protein 5 per cent but no rational systematic method of eradication is being used. An Indian reservation 21 miles up the river is a probable source as the Indians have had it for years with serious sequelae but only about 3 per cent of the adults that I have examined have any sequelae and only 0.5 per cent have active trachoma.

M D Nevada

ANSWER—This is a difficult problem, for the treatment of trachoma is an individual affair. General methods of treatment may be outlined, but these methods must be varied to fit the clinical condition in the individual case. In general cleanliness and prevention of secondary infection are of great importance. The first can be achieved only by the education of the infected individuals; the second can be attained by the constant and regular use by each patient of an eyewash of 1:5000 mercuric oxycyanide in distilled water from two to four times daily. In the individual case if follicles are present an expression should be performed. If there are not many follicles massage of the conjunctiva yields the best results. The eyes should be anesthetized and the tarsal and transitional fold conjunctiva rubbed vigorously, either with a plain smooth glass rod or else with a cotton wound applicator that has been saturated in chaulmoogra oil. The massage should be continued until the oil saponifies and should be repeated every two to five days, according to the severity of the disease. Powdered boric acid may be substituted for the oil. After all, it is probably the massage that is the efficacious factor. During the massage particular attention should be paid to the caruncle, Pannus, corneal ulceration and certain other complications are definite contraindications to vigorous massage. The sequelae should be treated as they arise. In conclusion, it is recommended that this condition be reported to the United States Public Health Service, which has physicians in the field to cope with such epidemics.

PHLEBITIS OR CELLULITIS

To the Editor—About two months ago a girl aged 16 years was struck by an automobile and an abrasion resulted about the size of a lemon on the lower part of the left leg. Also there was a large hematoma on the calf of the leg. A short time after this she was sent to the hospital because of chills and a temperature of 105 F. Hot packs were applied and the area of abrasion was opened with profuse drainage. White blood cells numbered 29,000 polymorphonuclears 89 per cent. Later an incision was made from the ankle to just above the knee and a foul necrotic area opened in its entirety. At present the white blood cells number 19,000 and the polymorphonuclears 69 per cent. The temperature is normal in the morning and afternoon but this necrotic purulent process continues to spread. Cultures of pus show staphylococci, streptococci and B. pyocyaneus. Scarlet red ointment, mercurochrome, merthiolate, surgical solution of chlorinated soda and hexylresorcinol S T 37 have been used. What would you suggest to stop this process? Is there any vaccine or therapy for B. pyocyaneus infection?

HUGH P. MUIR M D Columbia, Mo

ANSWER—It seems probable that following the local infection a phlebitis developed which suppurated and broke open. While a low grade cellulitis might explain the symptoms, it is likely

that phlebitis is the chief cause of the persistence of symptoms and the chronicity of the infection

Antiseptics on the surface of the wound are of little value in combating infection in the lymphatics or veins

The worst infection is undoubtedly the streptococcic, which is made more virulent by the other organisms

There is no vaccine used for pyococcus infections, which are not ordinarily serious alone. Vaccines would not seem to be indicated in this case

Extension to the bone with osteomyelitis occasionally occurs and a roentgenogram of the entire limb should be made

If the infection is limited to the soft parts it should be treated as a phlebitis or cellulitis. Incisions should be made for any pus pocket either in the veins or in the soft tissues. Heat usually by hot massive moist packs is often helpful together with absolute rest in bed with the leg elevated slightly

It may be necessary to open and possibly excise the saphenous vein throughout its extent if infected but it should be ligated high up before any manipulation. One should not ligate it until certain that the deeper veins are not also involved. In such a case prolonged rest in bed with general symptomatic treatment will usually result in recovery although a persisting edema of the leg may result

FUNCTIONS AND METABOLIC RATE OF NERVE FIBERS

To the Editor—Why is it that white nerve fiber is able to do so much with evidence of little metabolism while high nerve centers display high metabolism?

WALTER P. MOENNING, M.D., Indianapolis

ANSWER—The sole function of the nerve fibers is the conduction of impulses from one end to the other, or from the middle in both directions. The functions of the centers are much more complex, as shown by (1) polarity or irreversibility of conduction (only from afferent to efferent neurones), (2) considerable delay in the passage of impulses because of the cells and synaptic junctions, (3) great variability in irritability and in the magnitude of discharge, (4) alternation of excitatory and inhibitory discharges, (5) after discharge of impulses after stimulation is over and, most important, (6) the ability to form new functional connections, which underlies the development of conditioned reflexes and the phenomena of learning and memory. It is not surprising that the metabolic rate of the centers is many times greater than that of the fibers and that the centers are much more easily fatigued and are more profoundly affected by cessation of circulation (asphyxia) and by general anesthetics than are the nerve fibers

SINGER'S NODES

To the Editor—Please give me a statement by some authority dealing with the condition commonly referred to as singer's nose that is concerning the difficulty which a professional singer might experience from excessive use of his voice.

M. D. Indiana

ANSWER—Evidently the word "nose" is a typographical error, the term "nodes" being the proper one. This condition is characterized by the appearance of small white nodules or nodes on the vocal cords, most often situated at the junction of the anterior and middle thirds. The etiology is supposed to be the improper use of the voice, causing undue friction or contact between the cords. More complete details regarding the singer's nodes may be obtained by consulting the following references in the literature:

- Segre, R. Vocal Nodules as Revealed by Stroboscope *Valsalta* 9:380 (May) 1933

OBESITY AND PITUITARY EXTRACTS

To the Editor—I have a patient who is 24 years of age and weighs 250 pounds (123 Kg.). I have been having her take posterior pituitary tablets for the last three months and her weight came down to 220 pounds (99.7 Kg.) but now she is still taking the posterior pituitary gland product. Most of her weight is around the abdomen. What treatment do you advise now? Would whole pituitary be indicated? Please omit name.

M. D. Illinois

ANSWER—Most workers on obesity have not a great deal of faith in the value of any type of pituitary given by mouth. The basis of all reduction procedures must be a subcaloric diet. In the case under discussion, it would seem advisable to do a basal metabolism test and if there is a lowered rate thyroid extract is indicated with a reduced diet.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

- AMERICA BOARD OF DERMATOLOGY AND SYPHILIGOLOGY Clerks June Sec. Dr. C. Guy Lane 416 Marlboro St. Boston
 AMERICA BOARD OF OBSTETRICS AND GYNECOLOGY Officers (First B. Candidates) The examinations will be held in various cities of the United States and Canada, April 7. Oral (all candidates) Cleveland, June 12. Sec. Dr. Paul Titus 1015 Highland Bldg. Pittsburgh
 AMERICAN BOARD OF OPHTHALMOLOGY Cleveland June 11 Sec. Dr. William H. Wilder 122 S. Michigan Blvd. Chicago
 AMERICAN BOARD OF OTOLARYNGOLOGY Cleveland June 11 Sec. Dr. W. J. Wherry, 1500 Medical Arts Bldg. Omaha
 CALIFORNIA Los Angeles Feb. 26 March 1 Sec. Dr. Charles B. Pinkham 420 State Office Bldg. Sacramento
 CONNECTICUT Basic Science New Haven Feb. 10 Prerequisite to license examination Address: State Board of Healing Arts 1899 Yale Station New Haven
 ILLINOIS Chicago Jan. 23-25 Supt. of Regis. Dept. of Reg. and Edu. Mr. Eugene R. Schwartz Springfield
 IOWA Des Moines Feb. 20-22 Dir. Division of Licensure and Registration Capitol Bldg. Des Moines
 NATIONAL BOARD OF MEDICAL EXAMINERS The examinations in Parts I and II will be held at centers in the United States where there are five or more candidates Feb. 14-16 May 7-9 (limited to a few centers) June 25-27 and Sept. 12-14 Ex. Sec. Mr. Everett S. Elwood 225 S. 15th St. Philadelphia
 NEW YORK Albany Buffalo New York and Syracuse Jan. 29 Feb. 1 Chief Professional Examinations Bureau, Mr. Herbert J. Hamilton Room 315 Education Bldg. Albany

Book Notices

Paralysis in Children By R. G. Gordon, M.D., D.Sc., F.R.C.P., Physician, Bath and Wessex Orthopaedic Hospital, and M. Forrester Brown, M.D., M.S., Surgeon, Bath and Wessex Orthopaedic Hospital. Cloth Price \$1.50. Pp. 328, with 116 illustrations. New York & London: Oxford University Press, 1933.

In this volume on the paralysis of childhood the authors have correlated in a unique manner the neurologic with the orthopedic aspects. It is impossible to separate neurology from orthopedics if one is to have a complete understanding of the various types of paralysis. In order to treat these diseases adequately the orthopedist must know the neurologic changes underlying the paralysis. It enables him to prognosticate with greater finesse and to avoid unnecessary and useless reconstructive surgery. The book is divided into three parts. The first part deals with general subjects, such as the physiology of movement, the location of the neurologic lesion, the general pathology of paralysis and the interpretation of various syndromes. This part contains the most interesting diagrams, showing various neurologic schemes which clarify the physiology of the nervous system. In a composite manner aided by ingenious diagrams, the authors present the diseases and their particular points of attack in the central or peripheral nervous systems. The second part is entirely clinical and is replete with typical case histories of the various syndromes expressed in the different types of paralysis. Of especial interest is the presentation of the muscular dystrophies, anterior poliomyelitis and spastic paralysis. The third part is concerned with the treatment of paralysis in children and presents mostly physical therapeutic and nonoperative orthopedic measures. Although orthopedic operations are concisely discussed, the technical details are justifiably omitted because of the availability of extensive orthopedic works completely elaborating surgical detail. The authors are to be congratulated for their pioneer attempt to combine the neurologic and orthopedic points of view of paralysis in children.

Oeuvres de Pasteur Réunies par Pasteur Vallery Radot, professeur agrégé à la Faculté de médecine de Paris. Tome VI. Maladies virulentes, virus vaccins et prophylaxie de la rage. Fascicules I et II. Paper Price 160 francs. Pp. 906. Paris: Masson & Cie, 1933.

This volume (in two parts) of Pasteur's collected works contains practically everything that he published on infectious pathology in reports of learned societies and congresses and in medical journals. Here are given verbatim the famous discussions in 1874 in the Academy of Medicine on putrefaction and fermentation. Here are Pasteur's papers and reports on puerperal fever, furunculosis and osteomyelitis, on the anthrax bacillus and *Vibrio septique*, on vaccines against chicken cholera and anthrax, on rabies and antirabic treatment, beginning with experiments on the saliva of an infant dead of rabies. Finally come a series of documents relating to anthrax, including the experiments at Pouilly-le-Fort, and to rabies and antirabic vaccinations. This volume the next to the last of the complete works, contains writings that rank with those of greatest importance in medical literature. It always will be of fervent interest to physicians and biologists. Step by step are presented in original form the details of Pasteur's epochal achievements in the decade ended with 1886.

A Sixth Venereal Disease Climatic Bubo Lymphogranuloma Inguinale. Esthomiène, Chronic Ulcer and Elephantiasis of the Genito-Ano-Rectal Region. Inflammatory Stricture of the Rectum. By Hugh Stannus Stannus, M.D., Ph.D., F.R.C.P., Physician to the French Hospital, London. Cloth Price \$4.25. Pp. 270, with 16 illustrations. London: Baillière Tindall & Cox, 1933.

This compact volume which includes 933 references from the world literature, endeavors to expose properly what is known today about lymphogranuloma inguinale or the sixth venereal disease. The author acknowledges that it has already been termed the fourth venereal disease by several authors, as Lottrup in 1927, Cedercreutz in 1928 and Rezende in 1928. However he prefers to limit this term to the genital infection of Vincent's organism, then adding granuloma inguinale as the fifth disease and lymphogranuloma inguinale as the sixth. He states that the use of this term is no suggestion that it should be common usage. The author reviews the subject of climatic

bubo and lymphogranuloma inguinale bringing out their geographic, etiologic, clinical, bacteriologic and pathologic similarity. The intracutaneous reaction of Frei is carefully explained and its specificity for this disease discussed. As yet no specific treatment for the disease has been found. In later chapters the author develops the subject of later manifestations of lymphogranuloma inguinale—elephantiasis of the pudenda, esthiomene, the genito-anorectal syndrome and inflammatory stricture of the rectum. He takes the view that all inflammatory strictures of the rectum are due to lymphogranuloma inguinale. He discusses the many different names that have been given to the disease, and he thinks that the term lymphogranuloma inguinale is most unfortunate. He is inclined rather to accept the term 'poridontitis,' though he is not averse to the suggested name 'lymphopathia venerea.' On the whole, he has reviewed the literature carefully and covered the field quite fully. Throughout the entire volume the word 'gland' is employed where the accepted term is lymph node, e.g., the 'glands' in the groin. A too frequent use of abbreviations is noted. True, they simplify the work of the writer and perhaps of the reader if he is familiar with the terms, thus, C. B. (chlamydiae bubo), L. I. (lymphogranuloma inguinale), W. R. (Wassermann reaction), and K. I. (potassium iodide). The reviewer was not familiar with N. A. B. (p. 183). On page 155 and in several following places mention is made of the Dmelcos reaction, negative or positive. To an American medical reader this might not be sufficient explanation of a reaction to the chancroid organism vaccine (bacillus of Ducrey). Unfortunately, this valuable test is rarely employed in America and is almost unknown to the general practitioner. Some mistakes of the printer are to be found, especially with the use of foreign languages, notably German, as in reference 380 on page 233. The illustrations are only fair. On the whole, the book can be highly recommended to dermatologists, obstetricians, gynecologists, proctologists, surgeons, internists or general practitioners who are interested in a disease that is only just now being properly brought before the members of the medical profession.

Pathogenic Microorganisms. A Practical Manual for Students, Physicians and Health Officers. By William Hallock Park, M.D., Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College, New York City, and Anna Wessels Williams, M.D., Assistant Director of the Bureau of Laboratories of the Department of Health, New York City. Fifth edition. Cloth. Price \$7. Pp. 867 with 226 illustrations. Philadelphia: Lea & Febiger, 1933.

The high standard of this textbook of medical bacteriology and protozoology has been maintained in the present edition by a careful revision and an incorporation of the essential newer knowledge in the field. The wide experience of the authors allows them to furnish a critical opinion on numerous controversial subjects in bacteriology and public health. The enlargement of the section dealing with filtrable viruses is a welcome improvement, consistent with the more recently acquired information and the growing appreciation of their significance. While the volume is increased by fifty pages and several excellent illustrations, it is not too bulky. The arrangement of the chapters in a logical order of subjects is an improvement over the previous edition. The bacterial nomenclature is conservative and, although the book is remarkably free of typographic errors, one question why the generic name 'Hemophilus' is regularly spelled 'Hemophylus'.

Étude et traitement de la méningite tuberculeuse. Par Thérèse A. Jousset. Préface du Dr. André Jousset, professeur agrégé à la Faculté de médecine de Paris. Paper. Price 30 francs. Pp. 152 with 10 illustrations. Paris: Masson & Cie, 1933.

In four chapters the authoress thoroughly covers the most important problems pertaining to tuberculous meningitis—the etiologic and clinical features, the cerebrospinal fluid changes, the experimental and pathologic data and the treatment. In the last, most important, chapter she brings out the advantages of allergin in the treatment of tuberculous meningitis, a method introduced in 1927 by Prof. André Jousset of the Laennec Hospital in Paris. Allergin is a soluble extract of tubercle bacilli. It is a colloid substance and a veritable toxin which is totally different from tuberculin. Injected into the sub-

arachnoid space or hypodermically, it provokes a strong allergic reaction for a period of from ten to forty-eight hours. The existing signs and symptoms, such as coughing, aphonia and cerebrospinal manifestations, first become aggravated but soon subside and are followed by gradual improvement. When used early, before the tubercle bacilli have destroyed the ganglion cells, recovery sets in and the spinal fluid becomes normal. Histories of fifteen personal cases treated by the authoress with allergin are recorded with startling, almost unbelievably favorable, results. It is needless to state that the diagnosis of the cases treated and their clinical and serologic examinations, were carried out according to the most vigorous rules and that the subject was on the whole handled with extreme care and modesty. In view of the fact that, according to the statistics of the League of Nations, tuberculous meningitis causes in Europe annually 100,000 deaths, a scientific method of treatment that promises such wonderful results deserves the highest consideration as well as a thorough and extensive trial. Though details of the methods of preparation of allergin are not given in the monograph, the abundant bibliography may supply the necessary information.

Hirnehirurgie. Erfahrungen und Resultate. Herausgegeben von Dozent Dr. Hans Hoff, Assistent der Universitätsklinik für Neurologie und Psychiatrie in Wien, und Dozent Dr. Leopold Schönbrunner, Vorstand der chirurgischen Abteilung und des Strahlentherapeutischen Institutes des Krankenhauses der Stadt Wien. Mit einem Vorwort von Prof. Dr. Otto Lotzi, Vorstand der Universitätsklinik für Neurologie und Psychiatrie in Wien. Paper. Price 40 marks. Pp. 472 with 238 illustrations. Leipzig & Vienna: Franz Deuticke, 1933.

It is difficult to understand why this book was written except perhaps to give one of the authors (Hoff) the opportunity to discuss several more or less new reactions, little used and of doubtful value in the diagnosis of intracranial tumors. The title is misleading; it is not a treatise on surgery of the brain but is concerned almost exclusively with brain tumors. After some brief introductory sections concerning the history and general symptoms of brain tumors, the main body of the book consists of a series of case reports with some disjointed remarks about each. Fifty years ago such a collection of data might have been of some value, but today many American clinics could fill whole libraries with such case reports. No general conceptions emerge from this confused mass of material, although the author (Hoff) makes a feeble attempt to summarize beginning on page 344. The fourth and fifth sections are the work of a surgeon (Schönbrunner) who spent some months in Cushing's clinic, though evidence is lacking that he learned anything there. The technique described is antediluvian and its antiquity is reflected in the tabulation of results. The book serves no useful purpose except to bear eloquent testimony that the Viennese medical school, once the Mecca of the American postgraduate, has lagged far behind the progress of neurologic surgery.

Lehrbuch der gerichtlichen Medizin mit gleichmässiger Berücksichtigung der deutschen und österreichischen Gesetzgebung und des gemeinsamen Entwurfes 1927. Von Dr. Fritz Reuter, o. ö. Professor der gerichtlichen Medizin in Graz. Paper. Price 18 marks. Pp. 609 with 121 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1933.

As indicated in the title, this textbook on legal medicine is based on German and Austrian legislation. The book follows closely the traditions of the Vienna medicolegal school, and it is intended mainly for medical students and as a ready source of information about medicolegal problems for practitioners. The book opens with a discussion on a variety of legal matters of interest to the physician as such and as an expert or witness in medicolegal cases. Then comes a part on crime, the criminal, criminal psychology, personal responsibility, and allied questions. Forensic sexual problems, including abortion, receive extended and thorough treatment. The next section deals with the more general aspects of 'attacks on body and life' and leads to the consideration of the various forms of violent death and poisonings. The book will be of interest to medicolegal workers everywhere. It is an authoritative representation of medicolegal teaching and practice in the countries for which it is especially designed and the medicolegal methods and standards of which in essential respects are worthy of emulation in the United States.

Medicolegal

Dental Practice Acts Validity of Title of Act, Delegation of Legislative Powers—Hunt was prosecuted for practicing dentistry without a license. He was discharged on a writ of *habeas corpus*, the trial court holding the Florida dental practice act to be unconstitutional. The state appealed to the Supreme Court of Florida, Division A.

The practice of dentistry, said the Supreme Court, is not an absolute, unqualified or vested right, but is subordinate to the police power of the state. In the proper exercise of police power the legislature may control and reasonably regulate the practice of dentistry. The act under consideration the court continued, is not contrary to public policy nor is it within the domain of the exercise of police power. Hunt contended, however, that the title of the act violated a provision in the Florida constitution requiring the subject of an act to be briefly expressed in its title. The title of the act reads: "An Act to Regulate the Practice of Dentistry, Dental Surgery and Dental Hygiene in the State of Florida and to Provide Penalties for the Violation of Any of the Provisions of This Act." This title, it was argued, did not indicate that a board of dental examiners was to be created by the act, that fees were to be collected from applicants, and that large sums of money were to be collected by the board and expended in such manner as the board deemed proper. The point to be determined said the Supreme Court, is whether these matters are so irrelevant or unrelated to the subject of the act as expressed in the title as to violate the constitutional provision. When the title of an act expresses its subject with sufficient certainty as to give reasonable notice of matters dealt with by the act and of its scope and reasonably leads to inquiry as to its contents it is sufficient even though it is not an index to the act with respect to all its related provisions. To regulate the practice of a profession it is necessary to provide an elaborate if not complex machinery. The matters contained in the act here under review, which are urged by the defendant as invalidating the act are necessary incidents to or tend to make effective or to promote the object or purpose of the legislation of which the title gives reasonable notice to both legislators and the people and such matters may be regarded as properly connected with the subject of the act expressed in the title. The court concluded that the title did not violate the provisions of the constitution.

Section 9 of the act provides that an applicant for a license must be a graduate "from an accredited dental college as defined by the National Association of Dental Examiners." This provision Hunt contended, constituted an unconstitutional delegation of legislative authority to the National Association of Dental Examiners. The quoted clause, said the Supreme Court should be given a construction that will save it from condemnation. The legislature is presumed to have been in possession of the knowledge as to what dental colleges had been classed as accredited by the National Association of Dental Examiners. It is presumed to have been informed as to the meaning of the word "accredited" and its significance in this connection to the practice of dentistry in the state. Being thus informed and possessing the power the legislature may be considered as having directed by that clause that a person desiring to practice dentistry should submit proof of graduation from a college which may be classed as accredited as defined that is, as that term had already been defined by the National Association of Dental Examiners. Even if it should be maintained that the term as defined means a list of colleges already named by the national board there would be no objection to the act. In such case the conditions with which the applicant must comply will be definite, certain and not unreasonable. To sustain the defendant's contention continued the court that the clause constituted an unconstitutional delegation of legislative authority the court would be compelled to write into the act after the words as defined the following "or that may at any time hereafter be defined." This however, the court could not do. The term as defined if relating to colleges has reference to certain colleges then on the list as accredited colleges if it refers to the term "accredited" then it is left within the powers of the state board of examiners to determine whether the college

from which the applicant produces his diploma measures up to the definition of the term "accredited" as defined by the national board.

The Supreme Court of Florida concluded that the provision under consideration as construed by the court, attempted no unconstitutional delegation of legislative powers. The judgment of the court below in the *habeas corpus* proceedings, discharging Hunt was reversed and he was ordered remanded to the custody of the sheriff.—*Spencer v Hunt (Fla)*, 147 So 282

Unlicensed Practice of Medicine Enjoined—Dr Sloan, a licensed physician on behalf of himself and all other physicians similarly situated, filed a bill in the circuit court, Cabell County, W. Va., for an injunction to restrain Mitchell from continuing the unlicensed practice of medicine. Later two other licensed physicians practicing in the community in which Mitchell operated joined Dr Sloan as complainants. In the bill of complaint it was alleged among other things, that Mitchell had built up a large practice, had charged and received large sums of money for services rendered, and had thereby deprived the complainants and other licensed physicians of the opportunity of attending the patients thus treated. This the complainants alleged caused a loss of practice to them and a diminution in their professional incomes and a further diminution in their earnings and those of other licensed physicians might be anticipated unless Mitchell was restrained from continuing his activities. By his conduct and advertisements, Mitchell, it was further alleged, had degraded and injured the professional reputation of the complainants and would unless enjoined further injure their reputations and impair the monetary value of their licenses. The amount of damage done to the complainants by Mitchell's activities and the amount of damage that would result in the future if Mitchell should not be enjoined it was pointed out was uncertain. The legal remedy for such damages as they might thus sustain was therefore inadequate. A demurrer to the bill of complaint, interposed by Mitchell, was sustained by the trial court, and the complainants appealed to the Supreme Court of Appeals of West Virginia.

In our opinion said the Supreme Court of Appeals, the allegations contained in the complaint present a *prima facie* case for equity jurisdiction. The court cited with approval the case of *Dvorchen v Apartment House Association* 38 Ohio App 265 176 N. E. 577, decided by the court of appeals of Ohio, March 9 1931, which decision the Supreme Court of Ohio refused to review, by an order of June 10, 1931. In that case, the plaintiff a licensed attorney, instituted a suit for the benefit of himself and all other attorneys at law similarly situated to enjoin the defendant, a corporation, from practicing law in Ohio. The Ohio court said:

The right to practice law is an exclusive valuable privilege exclusive in that it is restricted to those who after special training and after examination and determination of special fitness are accorded the right to follow the profession of attorneys and counselors at law and valuable in that it carries with it the opportunity to secure material benefits and to earn a livelihood not given to those outside the profession. This right is in the nature of a franchise and a practicing attorney at law and others similarly situated have such an interest as members of the legal profession in the nature of a property right as will support the authority of such attorney at law to proceed as a proper party in an action to secure equitable relief against encroachment upon such right by a corporation.

Cases are legion continued the Supreme Court of Appeals of West Virginia holding that the right of a licensee to practice his profession is a property right, or a right in the nature of a property right, or a valuable franchise, or a valuable privilege. Although most of these cases are the outgrowth of proceedings for the revocation of professional licenses, their recognition of the high order of the licensee's right is as pertinent in a case such as the present one as they were in revocation proceedings. Again the fact that criminality is involved in certain conduct does not prevent a court of equity from entertaining jurisdiction to enjoin such conduct. While some courts emphasize the doctrine that equity will not ordinarily take cognizance of proceedings for the prevention of alleged improper conduct when the law has provided a statutory penalty for such conduct a more liberal and modern view has much to be said in its favor. Thus in *Kentucky State Board*

of *Dental Examiners v. Payne*, 213 Ky. 382, 281 S. W. 188, in which an unlicensed person was enjoined from practicing dentistry, the court said:

It is freely admitted that equity will not enjoin the commission of a crime as such as for instance it will not enjoin one from carrying concealed deadly weapons or from committing any other crime whether it be a felony or misdemeanor where nothing else is involved except the commission of the crime but where the chief purpose of the statute is to provide for the public welfare by regulating (not prohibiting) some already lawful calling and only provides a penalty for refusing to comply with such regulations and which penalty is enacted as a punishment for such refusal we can discover no logical reason why a court in administering the laws of its jurisdiction would be powerless to prevent the doing of the prohibited act merely because a penalty (only nominal in this case) is attached for a refusal to comply with the regulation.

The Supreme Court of Appeals therefore concluded that the trial court erred in sustaining the demurrer to the bill of complaint. Accordingly, it directed that the demurrer be overruled and the case proceed to trial.—*Loan v. Mitchell* (W. Va.) 168 S. E. 800

Fee Splitting Contrary to Sound Public Policy—A testator created trusts in favor of two hospitals, subject to a condition that each hospital adopt and enforce rules requiring all physicians practicing therein to pay to the hospital 10 per cent of their fees received for services performed in the institution. In a proceeding to settle the estate of the testator, the hospitals contended that the condition imposed on them a rule of conduct violative of public policy in that it compelled "fee splitting," a practice prohibited by the canons of ethics of the medical profession. It was also contended that the condition was impossible of enforcement and unreasonable, and that its application would result in the loss of the services of eminent physicians who would refuse to subscribe to the practice of fee splitting, with consequent impairment of the efficiency of the hospital in its treatment of free patients. Furthermore if the rule was enforced, it was claimed physicians would exact excessive fees in order to meet the additional payments to the hospitals. In the opinion of the surrogate court, New York County, N. Y., the condition sought to be imposed by the testator was obnoxious, contrary to the best interests of the community, impossible of performance and void. It is immaterial, said the court, whether the division of medical fees occurs between a physician and a hospital, or a physician and a physician, or between a physician and a hospital. In the latter case an outside agency participates financially in the compensation of the physician licensed by the state to practice medicine. Inevitably such a method of division would lead to deterioration in the medical staffs of hospitals with attendant injury to the public. Such a rule would likewise subject some physicians to the temptation of overcharging their patients in order to meet the requirements of the hospital rule. The court ordered the condition stricken from the will and the income of the trust created paid to the two hospitals free from any condition.—*In re Sterne's Estate* (N. Y.), 263 N. Y. S. 304

Evidence Impeachment of Medical Witness—In this case two police officers were charged with assaulting a prisoner in their custody. A physician was called to testify as to his examination of the prisoner, on whose body he found certain indications of violence. On direct examination he testified that the complaining witness in the case, the prisoner was brought to his office by a lawyer for whom he had testified in accident cases. On cross examination, he further testified that the lawyer had represented him in some matters of legal business and that he considered him a very good friend. Counsel for the police officers then proposed to ask the witness, the physician, if the lawyer had acted as his personal attorney in a proceeding before a grand jury involving a charge of abortion against the physician, which charge was subsequently dropped. The trial court sustained an objection to this question on the ground that it was too remote. In this ruling said the Court of Appeals of the District of Columbia, the trial court did not err. Furthermore, continued the court, in addition to the question being inherently improper, impeachment of the type here attempted proceeds on conviction not on indictment or attempted indictment and the physician witness had not been convicted of the crime involved. The particular question excluded could afford no basis for any legitimate inference impeaching the

credibility of the witness. It was clearly the right of the police officers to reveal the relation existing between the medical witness and the complaining witness in the prosecution and this had been done to a reasonable degree by showing the friend personal and professional relations existing between the physician and the lawyer who brought the witnesses together.—*Moslyn v. United States* (District of Columbia), 64 Fed. (2d) 115

Narcotics Indictment Must Specify Narcotic Drug Unlawfully Possessed—In Texas, the possession, sale or other distribution of narcotic drugs is prohibited by chapter 9, Acts of the Forty-Second Legislature, 1931. The term "narcotic drugs" is defined to mean opium, morphine, heroin, coca leaves, cocaine, marijuana, or any compound, manufacture, salt, derivative or preparation thereof. Under this act one Baker was convicted on an indictment charging that he "did unlawfully possess a narcotic drug" without naming the drug. He appealed to the court of criminal appeals of Texas, contending that the indictment was defective. While under the act, the court said, morphine, opium, heroin, coca leaves, cocaine and marijuana are all classed as narcotic drugs, it is manifest that an indictment in which an offense against the act is charged, should name the particular narcotic which the defendant is accused of possessing. In the absence of such an averment, the accused lacks information on which he may prepare his defense. Since the indictment in the present case failed, on its face, to name the particular narcotic it was insufficient. The judgment of conviction was reversed and the prosecution ordered dismissed.—*Baker v. State* (Texas), 38 S. W. (2d) 334

Malpractice Failure to Reduce Fracture No Evidence of Negligence—The plaintiff fractured his femur and the defendant-physician was employed to treat the case. He attempted for a period of about eighteen days to reduce the fracture by various means but his efforts were unsuccessful. The defendant was then dismissed and another physician employed who succeeded in getting the bones in apposition. A complete recovery followed. The plaintiff later instituted suit against the first physician the defendant in this case. The only expert witness who testified at the trial was the second physician, who reduced the fracture. At no time did he testify, however, that the treatment given by the defendant physician was not the ordinary and usual treatment generally used by physicians in that vicinity. At the conclusion of the plaintiff's testimony, the trial court directed a verdict for the defendant and the plaintiff appealed to the Supreme Court of Iowa.

Negligence on the part of a physician is not presumed but must be affirmatively proved, said the Supreme Court. The evidence in this case contained no criticism of the treatment administered by the defendant. No testimony was given showing any want of the use of the ordinary skill and care exercised by physicians generally in the community in which the defendant practiced. There was evidence that the fracture was not reduced by the defendant during the time he had charge of the case but no inference of negligence can be drawn from the fact that the treatment was unsuccessful or that it failed to produce the best results. Evidence was lacking, too, to show that what the defendant did or omitted to do caused the plaintiff to suffer pain. A complete recovery resulted and the plaintiff's only claim for damages, as shown by his petition, was for pain, mental anguish and nervousness, and for such, resulting from the original injury, the law does not permit him to recover. It follows, concluded the Supreme Court, that the trial court did not err in directing a verdict for the defendant.—*Hair v. Sorensen* (Iowa), 247 N. W. 651

AMERICAN

The Association library lends periodicals to fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Paroxysmal Pulmonary Hemorrhages—Oppenheimer and Schwartz report the cases of three young adults less than 30 years of age, suffering from chronic rheumatic cardiovalvular disease with mitral stenosis, who presented recurrent attacks of pulmonary hemorrhages. The attacks were characterized at times by an "aura" with psychogenic manifestations, severe pains between the shoulder blades, and palpitation of the heart. In one patient an urticarial rash ushered in the seizures. The onset of the attacks was usually during an afebrile period and came on many years after the first evidence of rheumatic fever. The attacks themselves were characterized by dyspnea, pain asthmatic breathing, cough and hemoptysis. At first the expectoration was frothy in nature, but later there were frank hemoptyses in quantities of from one to several hundred cubic centimeters of blood. The lungs during the seizures showed evidences of either localized or diffuse transudation in the alveoli, and there was a characteristic roentgen picture that was often mistaken for pneumonia. The attacks would last from one hour to several days and with their cessation the lung signs cleared up entirely. It was impossible to prevent the onset of the seizures in these patients by any medication. Morphine sulphate and atropine sulphate administered in adequate doses following the seizures seemed to allay the fear and abate the hemoptysis. Two of the patients died within three years following the onset of the recurrent episodes. In the one necropsy no bleeding point could be found. It is probable that in the absence of any embolic or thrombotic manifestations in the lungs, such seizures are the result of some reflex stimulation of the capillaries lining the alveoli resulting in hemorrhages from diapedesis, or possibly also from rupture of capillaries lining the walls of the bronchial tree.

Lead Inversion in Bundle-Branch Block—Nichol measured the QRS, the QE and the isometric period in eighteen normal persons, in seven cases of bundle branch block in which the QRS was upright in lead I and downward in lead III, in twenty-two cases with various types of disease of the heart but with a normal duration of ventricular excitation and in nine cases of disease of the heart with a prolonged period of ventricular excitation but in which the electrocardiogram was not typical of bundle-branch block. The electrocardiogram the subclavian pulse tracing from the left supraclavicular fossa and the apical heart sounds were registered simultaneously. Pulse tracings were recorded by a Frank segment capsule and

sounds by Wiggers' modification of Frank's method. The segment capsules were fixed approximately 92.5 cm from the recording camera and arranged in such a manner that the middle of the reflecting mirrors, the lens of the projecting microscope of the electrocardiogram and the lens of the camera were in the same horizontal plane. All records were checked for parallelism by Garten's method. No corrections were made when the effect due to parallax was less than 0.004 second. After suitable records were secured, lantern slides were made, projected on a screen with a magnification of from 10 to 12 diameters and the required intervals measured on the image with a celluloid ruler graduated in half millimeters. Determinations were made on three cycles in leads I and III. The intervals determined were (1) the duration of the main ventricular complex of the electrocardiogram, (2) the QE or the interval between the beginning of the QRS and the onset of the cardiac ejection phase as evidenced by the rise of the subclavian pulse tracing, and (3) the isometric contraction phase by Wiggers' method. In five of the seven cases of bundle-branch block the first sound was definitely reduplicated or split, but, as the first component of the reduplicated sound preceded the onset of ventricular excitation, it could hardly be attributed to asynchronous systole of the ventricles. In such cases the beginning of the second component was taken as indicative of the onset of ventricular contraction. The most pronounced doubling of the first sound occurred in a case presenting a PR interval of slightly more than 0.2 second. In a patient who showed a complete auriculoventricular block and ventricular complexes typical of the usual type of bundle-branch block, the first sound varied in intensity with the PQRS relations and there appeared to be a critical As-Vs interval at which doubling of the first sound appeared.

Polymorphous Sarcoma of the Uterus—Needles presents a case of polymorphous sarcoma of the uterus and reviews three from the literature. He states that the most reliable criterion in the diagnosis of these neoplasms is polymorphism as there is no principal type of cell. The four tumors occurred in women past middle age and the first symptoms were either vaginal bleeding or abdominal tumor. None of them were diagnosed until microscopic studies were made. The case of Kelly and Cullen was primary in a fibroid nodule, while Angier's, Masotti's and the author's cases seemed to arise from endometrium. Angier seemed to believe that his case had a close relation to the blood vessels, while Masotti denies any such evidence. The author summarizes by stating that polymorphous sarcoma of the uterus is an unusual tumor arising from the fibroid tissue, from the blood vessels or from the endometrial stroma. In gross appearance it is not different from many other tumors and is not to be distinguished from other sarcomas. Histologically, its chief feature is an extreme polymorphism of the types of cells. Oval, spindle, round and polygonal cells with giant cells and cells resembling endothelial elements are to be found. Care should be taken to examine many sections of sarcomas of the uterus in order that these tumors may be diagnosed when present. This is especially true of the so-called endotheliomas, giant cell tumors and those showing milder degrees of variation in the types of cells.

Treatment of Cancer of Cervix—Curtis demonstrates the feasibility of coincident surgical exposure and radium therapy in the treatment of extensive cervical cancer in three cases. Complete surgical recovery has occurred in one, with an accompanying gross disappearance of the growth and free mobility of a now apparently healthy uterus. One patient has made an almost complete surgical recovery, except for some irregularity in the contour of the uterus incident to partial destruction of the cervix and lower uterine segment. The other patient has at present some necrosis of the cervix and adjacent cellular tissues with considerable associated pelvic cellulitis and profuse discharge, which contains some fragments of tissue. The bladder and ureters are in excellent condition despite the nearby destructive process; this bladder would undoubtedly have been injured by the radiation had it not been spared by preliminary dissection and retraction at the time of treatment. When the surface has become free from necrosis and infection, a pelvic examination is made under anesthesia to determine the extent of the growth and the amount of intervention required and surgical exposure of the cancer-bearing uterus and adjacent cellular tissues is undertaken. The bladder is mobilized upward, the cervix encircled with an incision as in making a radical vaginal hysterectomy, and the vaginal mucosa dissected laterally and posteriorly, along natural lines of cleavage. Radium needles or radon seeds are inserted where needed and indicated, assuring the safety of the adjacent vulnerable organs. After the radium needles (or radon seeds) have been buried a chain tandem of radium capsules is inserted into the uterine canal in the usual manner. A vaginal pack completes the procedure. Until further experience warrants the total radiation should not exceed 3,500 millicuries. Even that amount may be excessive.

Reaction of Ovary to Anterior Pituitary-Like Principle—Geist gave fifty women between the ages of 30 and 48 from 600 to 2,200 rat units of anterior pituitary like principle from pregnancy urine, over a period varying from thirty-six to a hundred hours the administration of which resulted in definite changes in the ovaries. The injections were given subcutaneously, as much as 600 units being given in one day in divided doses. In a control series of twenty-five noninjected women the ovaries in four showed changes comparable to those found in the injected women. The ovaries of the injected patients presented a marked congestion of the vessels of the hilus with occasional extravasations into the hilus, probably due to rupture of small vessels or diapedesis. In the stroma there was also a marked increase in the vascularity and not infrequently hemorrhagic extravasation. Apparently there is no stimulation of the follicles; rather the follicles cease to develop beyond the point that they have reached at the time of the injection. The number of cystic follicles seems

increased. They are from 2 to 20 mm in diameter. The wall is smooth or thrown into small folds, the lining is glaucous or dark and pigmented and the cystic follicles are hemorrhagic. Occasionally the gross appearance suggests the positive Aschheim Zondek reaction in the rodent. In some specimens the epithelium is low, in others many layers of granulosa cells are present. Occasionally there is no demonstrable epithelial lining. Cast off masses of granulosa cells are found in the follicular fluid and the inner wall occasionally presents a granulosa layer that is being desquamated. In some sections, ripe follicles are arrested and show a cumulus with a degenerating ovum with hypertrophy of the thecal cell. The theca lutein cells in many instances are prominent and increased in number. Occasionally a yellow body is found with massive hemorrhage into it. The intensity of the reaction in the ovary seems to bear a direct relationship to the amount of hormone injected. The patients who received the injection over a period of ninety-six hours or more seemed to be most affected. In normal pregnancy the ovaries present changes somewhat similar to the foregoing and it is possible that this similarity is dependent on the same factor, the increased anterior pituitary-like hormone in the blood.

Effects of Theelin on Gonorrheal Vaginitis—Lewis used theelin in the treatment of eight children suffering from severe vaginal infections accompanied by a purulent discharge (typical gonococcus vaginal infection). Smears showing gram-negative intracellular diplococci morphologically resembling gonococci were taken as a criterion for the diagnosis of gonococcal infection. Positive cultures were not obtained from the vagina. One of the children presented a typical gonococcal arthritis and positive cultures were secured from the aspirated knee joint involved. In another child aged 5 days, a typical gonococcal ophthalmitis developed followed in twenty-two days by vaginal infection. In the eight children constituting this series no other form of treatment was employed while theelin was being given. The vulvar surface was sponged with saline solution when it became fouled with vaginal secretions. Four of the patients gave histories of recent infection, the others of from six to twenty months. The patients received daily one, two or three hypodermic injections of theelin of 50 rat units in the arm or leg. The total dosage of theelin, as well as the duration of its administration required to arrest all vaginal discharge and cause the gonococci to disappear from the vaginal smears, varied. In four patients having infections of long standing, theelin was given for ten or twelve successive days only, the total amounts varying between 850 and 1,000 rat units. The child who was given 1,000 rat units hypodermically received also approximately 250 rat units by vaginal suppositories. These children had been treated previously with local antiseptics. In the other four patients, larger quantities of theelin given over a longer period were necessary to arrest the vaginal discharge and to yield smears negative for gonococci. The patient receiving the least amount of theelin was given over a period of nineteen days a total of 2,800 rat units hypodermically and 450 rat units by vaginal suppositories. The leukorrhea stopped soon after treatment was begun and smears became negative after twenty days. There was no recurrence of symptoms at the end of the four months. Another child received 100 rat units daily for thirty-one days. The discharge ceased and smears became negative on the twenty-sixth day. The longest course of treatment continued for ninety-eight days. During this time with occasional interruptions 8,450 rat units of theelin was given hypodermically and 250 rat units by vaginal suppositories. No local irritation resulted from the administration of theelin nor were there unfavorable general symptoms. The children receiving the larger amounts of theelin exhibited a hypertrophy and an increased vascularity of the labia majora and minora and of the introitus which resembled the conditions found in the newborn child. In no case did uterine bleeding result from or follow the treatment with theelin. In the majority of the cases vaginal discharge ceased in one to three weeks after treatment was instituted. At the conclusion of treatment the discharge was absent in all eight patients and smears were negative for gonococci. Desquamation of epithelial cells in large numbers was usually found in from seven to twenty-one days.

Calcification in Aortic and Mitral Valves—Sosman and Wosika state that the roentgenoscopic and roentgenographic visualization of calcified heart valves during life is possible with present-day roentgen apparatus Aortic stenosis with calcification is a common observation in older patients Calcification in

the leaflets of the mitral valve is accompanied by definite signs of mitral stenosis Calcification in the fibrous ring of the mitral valve, at least, may be entirely unrelated to disease of the cusps and produce no cardiac symptoms For roentgenoscopy adequate preparation of the eyes is essential, a beam of rays of fairly high penetration is required, a small aperture is necessary both to concentrate the attention and to cut down secondary radiation and the position of the patient is important, as the dark areas of calcification can best be seen with the patient rotated so that the right shoulder is from 15 to 20 degrees forward a modified right antero-oblique position In roentgenography the most confusing shadows are those of the calcified costal cartilages so common in older persons These may be so extensive and so marked that it is impossible to be certain of the shadow of calcified valves which were seen clearly during roentgenoscopy Here too, calcified glands and calcified areas in the lung may be confused with the shadows cast by the calcified valves The film should be used only to check the amount and distribution of the calcification and to furnish a permanent record for demonstration

Physical Foundations of Chest Roentgenography—Wilsey states that the sharpness of outline of roentgen shadows of the tissues of the lung is governed chiefly by the movement of the tissues with the heart beat and the size of the focal spot of the roentgen tube The mutual adjustment of these factors to produce the best resultant sharpness may be worked out by the analytic method of Bouwers The application of this method to roentgenography of the chest indicates that, in the main the times of exposure giving the best definition or sharpness of lung tissue are in the neighborhood of one-twentieth second The analysis also shows that the best prospects for marked improvement in sharpness lie in the use of a rotating target line focus roentgen tube and in the synchronization of the exposure with the phase of minimum movement of the lung, as proposed by McPhedran and Wevl The latter procedure has the additional merits of permitting longer times of exposure decreasing the power required of the roentgen machine and minimizing the distortion in the stereoscopic image caused by movement of the lung tissues between stereoscopic exposures

A Sign of Early Cell Necrosis in Mastoiditis—Berg and Constans describe a new sign of early cell necrosis In checking the surgical observations and the mastoid roentgenograms immediately after the operation, they noticed that cases not showing frank cellular necrosis roentgenologically, but in

which the walls of the cells showed the following roentgen changes, were necrotic (1) the walls of the cells would appear to be slightly widened, (2) the density of the walls of the cells seemed to be slightly increased, (3) the edge of the walls of the cells would show a fine fuzziness and (4) the walls of the cells could be traced out completely. The authors observed this sign in eleven cases of their series that showed the four foregoing changes in the walls of the cells. Ten of these showed necrosis of the walls of the cells at operation. In the other case the cells contained pus and the walls of the cells appeared to be intact.

Therapy of Actinomycosis—From a study of the literature and their observation of eight cases Archer and Barker state that the response to therapy directed against actinomycosis varies with the anatomic location. Cervicofacial involvement almost invariably responds well to surgical curettage, iodide and roentgen irradiation and frequently even to surgery alone, when the disease is well localized. When there is more extensive involvement, iodides and radiation therapy should be used as adjuncts to surgery, since complete surgical extirpation of the diseased tissues would be impossible on account of the complex cervicofacial anatomy and facial disfigurement. The cases of actinomycosis with thoracic and abdominal involvement present a different problem. Surgery in these cases plays a minor part and should be used only to evacuate pus and to establish drainage. Massive doses of iodides and roentgen irradiation are the principal therapeutic agencies. The results in these patients are not brilliant but sufficient improvement has been noted to warrant the continuation of this method of treatment until the advent of a more satisfactory therapeutic regimen. Since thoracic and abdominal cases are usually not diagnosed until there is extensive involvement it is apparent that one cannot hope for complete surgical removal of all the diseased tissue. This being true too radical surgery with dissection of all sinus tracts would tend to spread the process rather than to effect a cure. The best results in this type of case seem to be obtained by keeping these patients continuously on iodides by mouth up to the limit of tolerance, combined with roentgen irradiation, and by using surgery only for the evacuation of collections of pus.

Splanchnic Nerve Section in a Diabetic Patient—De Takats and Fenn performed bilateral splanchnic section on an 18 year old diabetic girl to stabilize and increase her sugar tolerance. There has been an immediate drop to one half of her previous insulin requirement, which seems to be due to an increase in insulin sensitivity and which has persisted for four months after the operation. The operation resulted in an abrupt change of the dextrose insulin ratio of the diabetic child from 25:1 to 5:1. This change occurred after section of the left splanchnic nerves, whereas the later sectioning of the right splanchnic nerves did not produce any further improvement. During the postoperative period of four months the patient's weight increased 15 pounds (6.8 Kg). It is of some significance that several subsequent attacks of infection of the upper respiratory tract did not upset her insulin requirement. This now seems to be stabilized at from 20 to 25 units for a diet of 120 Gm of available dextrose.

Diagnostic Use of Iodine in Thyrotoxicosis—Means emphasizes the fact that iodine is a helpful agent in the diag-

nosis of thyrotoxicosis as well as in its treatment. Whenever there is any doubt or question of its presence the effect of iodine should be observed. Isolated basal metabolic rates are not enough. Sufficient data to observe definite levels and trends must be obtained. The absolute level is of little significance. The fluctuation is what counts. A drop from plus 9 to minus 8 with iodine and return to plus 9 when the drug is stopped is significant. When thyrotoxicosis is truly present, even though in a slight degree, the response to iodine is definite, delicate and exact.

Psoriasis of Mucous Membranes—Usher reports two cases of psoriasis of the mucous membranes. The features of the first case that were suggestive of the psoriatic nature of the lesions on the surface of the tongue were the clinical course closely paralleling that of the eruption on the body, the absence of irritating factors, such as syphilis and tobacco, which might account for leukoplakia, the desquamation of the epithelium with prompt recurrence, and the changes seen in the histologic section. While the sections were not entirely typical, their chief features—acanthosis, papillomatosis and parakeratosis—made the condition compatible with psoriasis, especially when one took into consideration the maceration that affects a lesion on the under surface of the tongue. The diseases that one might consider—leukoplakia, geographic tongue, lichen planus or an infection due to yeast—could be ruled out without difficulty because of the clinical course of the eruption and because of the laboratory observations. In the second patient the diagnosis of psoriasis was made with a certain degree of reservation. The overlying epithelium unlike that of the first case, could be scraped off only with difficulty and the underlying bleeding was not characteristic. Moreover, the histologic sections from the mouth were not characteristic of psoriasis and were not similar to those from the body. From the sections alone a diagnosis of leukoplakia could be made. Against a diagnosis of leukoplakia were the sex and the age of the patient and the absence of syphilis, excessive smoking or other irritative factors. The diagnosis of buccal psoriasis was made entirely from the clinical course of the eruption. The coincidental appearance of the lesions on the mucosa and on the body, their reaction to treatment with a gold compound with no local therapy, and their subsidence would appear to substantiate the diagnosis of psoriasis.

Gold Compounds in Treatment of Lupus Erythematosus—Following the report of Monash and Traub, Jones and Alden began treatment in a case of lupus erythematosus adhering to their technique except that they employed a prepared aqueous solution of gold sodium thiosulphate. Owing to the limited supply of this preparation they began to treat only a part of the diseased skin, i. e., one side of the face. After

three weekly intradermal injections of 10 mg each, improvement was manifest, but strangely the improvement occurred on the side of the face that had not been treated. The patient complained of the discomfort of multiple needle punctures and recourse was had to a single subcutaneous injection in the upper part of the arm. Improvement progressed with the continuance of this manner of giving the drug, and the patient complained of little discomfort at the site of the injection. Four additional patients having lupus erythematosus were treated. The treatment was similarly successful. Not more than 25 mg of the drug was given at weekly intervals. A patient with a long-standing case of lupus vulgaris to whom extensive treatment had been given previously was also treated both intradermally and subcutaneously with no apparent effect on the disease. Intramuscular injection of the gold preparation was attempted, but the patient complained of far more pain and discomfort than when it was given subcutaneously. All these patients are under treatment at the present time, and all have presented immediate good results.

Roentgen Treatment of Primary Lesion of Tularemia
—Baer treated two primary lesions of tularemia on or about the third day with a dose of a half unit of unfiltered x-rays over the affected area. In the first patient, hot wet dressings of boric acid were applied to the thumb and arm. The pain, which affected the thumb and extended up the arm had ceased three hours after the roentgen treatment. On the following day the redness and swelling of the thumb, together with the lymphangitis and tenderness, had disappeared. The temperature and pulse rate became normal. There was no axillary tenderness. The patient made an uneventful recovery. On the first day of examination the agglutination test for tularemia was negative. The agglutination test taken about thirteen days after the inoculation gave a reading of 1:320. Two months later the agglutination test was positive, 1:80. In the other patient the pain in the finger subsided six hours after treatment. The temperature and pulse rate became normal. He made an uneventful recovery. The first agglutination test for tularemia was negative. About fourteen days after inoculation the reading was positive, 1:160, and six weeks later 1:80.

Treatment of Peptic Ulcer with Okra—The experience of Meyer and his associates with powdered okra, in a selected group of carefully studied peptic ulcer patients, points to the relief of the predominating symptoms of pain and gastric discomfort following a short period of administration. This confirms the recent report of Jones, Ivy and Atkinson. The relief of symptoms despite an active acid response in a greater number of the authors' patients (72 per cent) may seem at first difficult to interpret. It has been shown by one of them that the pain of gastric ulcer is independent of acid secretion. They suggest that the associated gastritis is the principal cause of pain. It is likely that the okra relieves the symptoms by alleviating this gastritis and duodenitis. These observations are in accord with the remarks of Mathieu, who raised the question as to whether the favorable results obtained by the use of agar mucin were due to some other factor than a mechanical one. The authors' observation in dogs of the decreased emptying time of the stomach following the administration of okra suggests that this also may be an important factor in the relief of symptoms. The increased acid response to okra in a greater number of their patients (72 per cent) and in 50 per cent of normal students suggests a striking similarity to the results obtained by Rivers and others on using impure gastric mucin. Whether this vegetable contains a histamine-like substance is now being studied. It is striking that in but two instances were the symptoms (such as heartburn) following the use of okra sufficient to warrant its discontinuance.

Immunity After Abolition of Allergy—Rich and his associates carried out experiments on *Pasteurella aviseptica* and pneumococcal infection to determine whether immunity would be any the less efficient after the abolition of allergy by desensitization. When the capacity for reacting with allergic inflammation is completely destroyed by the injection of large doses of killed bacteria into the veins of hypersensitive immune animals immunity to intracutaneous infection with millions of lethal doses of living virulent bacteria remains intact. Inflam-

mation at the site of infection in such animals is far less in amount than in untreated allergic immune animals—far less, indeed, than in normal controls but the bacteria are prevented from spreading from the site and are as effectively destroyed as they are in the allergic immune body. The immune state acts to enhance the protective power of the inflammatory mechanism so that much less, rather than much more, inflammation is required to protect the body from infection. Damage to the tissue at the site of infection is also far less in the desensitized animals than in the allergic ones. Even in the highly allergic immune body therefore allergic inflammation is not necessary for protection against infection, and in its absence the body is protected with much less damage to the tissue than that which occurs in the allergic body.

Extra-Articular Arthrodesis of Shoulder—Jones describes an operation by which solid bony fusion can be secured without opening the joint, and the arthrodesis is definitely extra-articular. Three cases are reported in which a sufficient interval of time has elapsed to judge the operation. In no case was there any aggravation of the disease or recurrence elsewhere and in all three cases bony ankylosis resulted. A straight incision is made over the point of the shoulder, centering on the tip of the acromion. It extends upward for about 3 inches midway between the clavicle and the spine of the scapula, and downward for a similar distance toward the deltoid insertion. The flaps are dissected sufficiently to expose the whole of the outer surface of the upper 3 inches of the humerus, the outer third of the clavicle, the acromioclavicular joint and the outer third of the spine of the scapula. The deltoid is separated subperiosteally from the clavicle, acromion and scapula and the fibromuscular flap is turned downward. Both upper and lower surfaces of the acromion are freshened by removal of the cortical layer of bone. A broad flap of bone 1 inch wide and 2 inches long is raised from the outer surface of the upper end of the humerus by driving an osteotome vertically into the upper part of the greater tuberosity immediately

beyond the capsular attachment, the osteotome being held in the long axis of the humerus. The flap of bone is gently levered outward but is not completely fractured at its base, so that when the osteotome is removed the flap tends to spring back into position. The clavicle and the spine of the scapula are partly fractured a few inches from their outer ends. The arm is abducted and the whole acromioclavicular mass is angulated downward, hinging at the point where the bones were half fractured. It is wedged underneath the flap of bone raised from the humerus, so that its raw, freshened surfaces are impacted into the cancellous bone of the upper shaft of the humerus. Fixation may be augmented by a few strong sutures, and, if necessary, chips of bone or osteoperiosteal grafts from the tibia may be implanted. The wound is closed in layers and the limb is encased in a plaster spica cast in a position of 80 degrees of abduction, 30 degrees of forward flexion and 30 degrees of external rotation.

Fractures of Neck of Femur—Leadbetter suggests a method for the manipulation of fractures of the neck of the femur in which the patient is anesthetized, the uninjured leg is harnessed to the foot stirrup and flexed at the hip at 90 degrees with the lower leg at 90 degrees to the thigh and direct manual traction in the axis of the flexed thigh is made, together with slight adduction of the femoral shaft. The thigh is internally rotated approximately 45 degrees. The leg is slowly circumducted into abduction, the internally rotated position being maintained. The amount of abduction varies with the patient and can be measured accurately representing the difference in degrees of the angle made by the fractured neck of the femur with the shaft and the angle between the neck and the shaft on the normal side, as evidenced by the roentgenogram. After the leg has been brought down in the measured degree of abduction and internal rotation the heel of the injured leg is allowed to rest on the outstretched palm. If the reduction is complete the leg will not exert itself. Should there be no interlocking of the fragments, the leg will slowly rotate externally.

Hip Fusion Operation—Chandler outlines an operation for the obliteration of the hip joint and the development of an extensive area of fusion. The patient is placed on the well side at an angle of about 45 degrees. A long vertical incision is made over the lateral aspect of the hip extending from the crest of the ilium directly over the greater trochanter to the juncture of the upper and middle thirds of the thigh. The incision is carried through the subcutaneous tissue and splits the tensor of the fascia lata exposing the lateral aspect of the greater trochanter, the gluteus medius and the origin of the vastus lateralis. The incision is then carried through the periosteum and origin of the vastus lateralis and through the midportion of the gluteus medius, parallel to the muscle fiber. It is deepened to the superior aspect of the femoral neck and crosses the hip joint at right angles to the upper acetabular margin. Heavy flaps of bone attached to the periosteum and muscle insertions are then elevated from the anterolateral and posterolateral aspects of the greater trochanter and the upper end of the shaft. The capsule and periosteum of the femoral neck are elevated anteriorly and posteriorly from the line of incision. These flaps are retracted anteriorly and posteriorly, exposing the trochanter. A massive graft, consisting of the main portion of the greater trochanter and the lateral cortex of the upper portion of the femoral shaft, is removed by parallel cuts which converge in cross section through the cortex and cancellous tissue. The capsule is stripped from the superior margins of the acetabulum. A curved arthroplasty chisel is used to denude the surface of the femoral head and the opposing articular cartilage of the acetabulum. Fragments of cancellous bone taken from the bed of the graft are firmly pressed into this space. A hinged flap of bone is elevated from the outer table of the ilium just above the acetabular margin, and a recess made in the ilium to receive the cortical portion of the graft. The graft is then turned end for end and the cortical portion driven into the recess above the acetabulum. Better contact can be secured if the thigh is abducted. The trochanteric portion of the graft will make contact with the graft bed in the upper end of the femur when the thigh is in a natural position or slightly abducted. With the graft in

place, the hinged osteoperiosteal flaps removed from the trochanter are brought into position covering the free end of the graft. The periosteum and origin of the vastus lateralis are sutured, the fascial, subcutaneous tissues and skin are loosely sutured, and a double spica cast is applied to hold the thigh in the position of election until bony fusion is complete.

Acromioclavicular Dislocation—In the reconstruction of the acromioclavicular joint, Schneider prefers fascial flaps taken from the lower two thirds of the thigh so as to include the iliotibial band. The fascial strip, 8 inches long and three-fourths inch wide, tapered at each end, is removed and split longitudinally in two pieces one-half inch and one-fourth inch in width, respectively. These are placed in saline solution and the fascial sheath is closed with a continuous number 1 chromic catgut suture, followed by skin closure. Approach to the acromioclavicular joint and coracoid process is made through a 4 inch incision at the inferior outer margin of the clavicle, curved downward at the anterior margin of the deltoid. The superior acromioclavicular ligament is dissected off the upper surface of the acromion from the articular surface laterad for about one-half inch. Two three-sixteenths inch drill holes equidistant from the articular margin, are made in the acromion and two similar holes are drilled in the clavicle at the same distance from the joint. Restoration of the inferior acromioclavicular ligament is accomplished with a mattress suture of the one-fourth inch fascial loop, each end of which is carried downward through a clavicular drill hole, laterad across the inferior surface of the joint and up through its respective drill hole in the acromion. The ends of this loop are then crossed on the superior surface of the acromion and sutured to each other with twisted silk. Next the coracoclavicular ligaments are reconstructed by carrying the one-half inch fascial strip under the inferior surface of the coracoid process upward behind the clavicle subperiosteally at the site of insertion of the trapezoid and crossed on the superior surface of the clavicle, where the loop, under tension is sutured with braided silk. The ends of this loop are drawn along the superior surface across the acromioclavicular joint and sutured together with silk to the acromial end of the acromioclavicular ligament, previously dissected up, thus restoring the ligament. The muscle and skin are closed in layers, the wound is dressed, and a Dillehunt cast is applied for immobilization. The author reports two cases of reconstruction of the acromioclavicular joint in professional athletes in whom he employed this method.

Arthrodesis of Shoulder Joint—Brett states that contractions must first be overcome by maintaining the arm in abduction in a plaster bandage previous to surgical intervention. He has obtained a complete range of motion in two patients who have been able to resume laborious work within a period of four months following the arthrodesis by the following technic. A curved skin incision over the shoulder joint, or a straight incision beginning high above the acromion and running downward parallel to the shaft of the humerus, may be used. The fascia is incised and the tissues and muscles are freed and retracted. The capsule is split longitudinally and dissected back from its attachment on the anatomic neck of the humerus, except for the portion about the posterior third of the bone. The head is then forced out of the glenoid cavity by rotating the arm outward. The surfaces of the head glenoid and under side of the acromion are carefully denuded of cartilage, so that the cancellous bony structures are exposed. The cartilage on the peripheral edges of the glenoid should be removed so that bony contact can be established with the head. With the arm in from 70 to 80 degrees of abduction and in from 20 to 30 degrees of forward flexion a hole about one-fourth inch is drilled from just below the greater tuberosity through the humeral head in line with the center of the glenoid, then through the glenoid and finally into the spine of the scapula, until the end of the drill is palpable in the outer scapular musculature. A massive graft three-eighths inch in width and varying in length from 3 to 5 inches taken from the tibia is shaped so that it will fit snugly. A hole is drilled through the upper border of the head and glenoid and the humerus is tied in place with kangaroo tendon. The graft is driven through the head and glenoid and out through the spine of the scapula, until it is palpable at the end of the drill hole.

The acromion process is broken down in the manner of a greenstick fracture and fixed to the head by means of stay sutures of number 3 chromic catgut or kangaroo tendon, which are passed through the drill holes. The capsule is sutured down on the humerus for further stability. The musculature and skin are sutured. A well fitting plaster spica cast, embracing the shoulder and chest down to the umbilicus and extending from the neck to the fingers is applied with the shoulder in the position of from 70 to 80 degrees of abduction and from 20 to 30 degrees forward of the frontal plane. At the end of two months, the upper half of the cast is removed to permit braking and massage, and the patient is instructed to begin raising and lowering his arm voluntarily. At the end of from two to four weeks, the entire cast is removed and exercises are given daily to produce hypertrophy of the scapular muscles.

Arthroplasty of the Elbow—Albee presents a method of arthroplasty of the elbow which has the following advantages: 1. The approach gives the freest exposure possible without jeopardizing important structures. This point cannot be too highly emphasized, because the success of the operation depends on the most meticulous care in the removal of all peripheral bone (especially in front of the joint) and the suture of the interposed fascia-fat graft. 2. It enables the surgeon to remove a sufficient amount of bone to insure complete freedom of motion without jeopardizing stability. Stability is brought about by the antagonistic pull of the flexors and extensors on a lever of which the fulcrum comes at the newly formed joint and the posterior arm (the olecranon) is long enough to allow a sufficient antagonistic action of the triceps to bring this about. 3. Early immobilization without danger of separation or non-union of the ulnar parts is made possible by using a long, sliding inlay olecranon-ulna graft to which the insertion of the triceps is undisturbed and an accurate mortise fit of this graft into its proper gutter.

Intranasal Virulence of Pneumococci—The experiments of Webster and Clow show that smooth colony pneumococci fresh from human beings, instilled in small doses into the nasal passages of mice raised under standard conditions, brought about a characteristic infection which spread to healthy contacts inciting in them the carrier state or fatal infection. Differences in response by individual hosts to the same dose of a given culture ranged from a complete refractory or nasopharyngeal carrier state, or a local cervical lymphadenitis to fatal lobular or lobar pneumonias with or without pleurisy, empyema and pericarditis, and acute fatal septicemia. Pneumococci exhibited consistent individual strain differences with respect to ability to infect when instilled intranasally into mice, and also differences in the spread to contacts. Degree of intranasal virulence paralleled demonstrable ability to spread to contacts. The degree of intranasal virulence of the strains did not parallel intraperitoneal virulence in 50 per cent of the strains—high intranasal virulence was accompanied by either high or moderate intraperitoneal virulence, and low intranasal by high moderate or low intraperitoneal virulence. Type III strains were of relatively high intranasal and intraperitoneal virulence; type II strains were mostly low in intranasal but

high or moderate in intraperitoneal virulence and type I strains were all low in intranasal but either high or moderate in intraperitoneal virulence. Most of the strains of other types were low both in intranasal and in intraperitoneal virulence. The intranasal virulence of pneumococci was not enhanced by animal passage. Nasal passage reduced the intranasal virulence to zero but did not affect intraperitoneal virulence, colony form and agglutinative specificity. Passage by the intraperitoneal method maintained the characteristic level of intranasal virulence for a period and increased intraperitoneal virulence in some instances but did not affect colony form or agglutinative properties.

Fibrinolytic Activity of Hemolytic Streptococci.—Illett and Garner tested twenty eight strains of Streptococcus hemolyticus, isolated from patients suffering from various manifestations of streptococcal infection for the capacity to liquefy fibrin clot. Broth cultures of all the strains induced fibrinolysis. Of eighteen strains of Streptococcus hemolyticus of animal origin only three were capable of causing dissolution of clot. Completely negative results were obtained with thirty-eight strains of other bacterial species. The plasma of many patients recovered from acute hemolytic streptococcal infections when clotted in the presence of active cultures is highly resistant to fibrinolysis. Furthermore serum derived from patients whose plasma clot is resistant often confers on normal plasma clot an antifibrinolytic property. One example of the resistance possessed by the blood of convalescent patients is presented. In contrast to the susceptibility of normal human fibrin clot to liquefaction by active culture, normal rabbit fibrin clot is totally resistant to dissolution when tested under comparable conditions. The insusceptibility of rabbit fibrin clot is manifest provided the coagulatum is composed of rabbit constituents. When human thrombin is used to clot rabbit plasma or fibrinogen in the presence of active cultures, fibrinolysis is not prohibited. The part of thrombin in determining the resistance or susceptibility of rabbit fibrin to dissolution offers a suggestive approach to problems relating to the underlying mechanism.

Transplantation of Ureters into Intestine.—Brady and Shaw cite three cases of complete urinary incontinence in which the ureters were implanted into the sigmoid. In none was it possible to restore urinary control by any simpler operative procedure. In one case the transplantation was entirely successful and the patient is leading a perfectly normal life two years after operation. One patient died two months later of peritonitis and an ascending genito urinary infection. At operation the sigmoid was found badly inflamed and adherent to a left tubo-ovarian abscess, which was removed. The third patient had complete urinary control for almost two years but succumbed to a subsequent condition in no way directly associated with the implantation (carcinoma of the bladder). The authors believe that if this patient had not developed carcinoma she would have enjoyed many years of normal life after this operation. Since the bladder was not exposed to trauma as is the case in instances of exstrophy of the bladder, there was no reason to suppose that a malignant condition would be especially apt to develop in this area. Most urologists admit that Coffey's operation offers the best results in cases of exstrophy of the bladder. However, many authors feel that whenever a ureter is implanted into the rectum severe infection of the ureter and kidney will follow and that hydro ureter and hydronephrosis

will develop in the vast majority of instances. The authors' almost negative observations in their second case that came to necropsy do not substantiate this opinion. Their experience definitely encourages implantation of the ureters into the intestine together with cystectomy, in cases of exstrophy and in selected cases of carcinoma of the bladder, provided there is no infection or malignant invasion of the lower part of the intestine.

Operation for Retroversion of Uterus.—Hetherington describes an operation for the correction of retroversion and the obliteration of some of the varicose veins and the straightening of the other veins of the broad ligaments in which a median incision is made and the intestines are packed back with gauze. Two incisions are made about three fourths inch apart, the upper ends of which begin opposite the insertion of the round ligaments and are carried down the anterior wall of the uterus about 2 inches, one eighth inch deep into the musculature of the uterus. A flap is raised about an eighth of an inch thick the length of the two incisions. A long hemostat is passed under the flap and the round ligament grasped far enough from its insertion with the fundus of the uterus so that it can be pulled straight across to the opposite side beneath the flap. This carries the fold of the broad ligament with it. The round ligament is anchored to the uterus at the outer edge of the incision with number 2 formalized or chromic catgut a round curved needle being used which is inserted about one fourth inch from the margin of the incision dipped well into the uterine wall and brought out just under the edge of the flap and through the bend of the round ligament. This suture should be tied. The round ligament is seized with a hemostat at a point below equal to the length of the incision drawn through as above and sutured. One or two intermediate sutures are taken. The forceps is now passed under the flap from the opposite side and the free round ligament with the broad ligament is brought through and over the first suture line and anchored in the same manner as before except that the interrupted sutures are passed through the broad ligament into the

uterine wall and emerge through the free edge of the flap. The round and broad ligaments are drawn through at the lower end of the flap and anchored with two or three more interrupted sutures. A like line of suture is passed through the free edge of the flap on the other side, going through both layers of broad ligaments and into the wall of the uterus. Three or four interrupted sutures will close the wound and complete the operation.

Thyroidectomy in Heart Failure and Angina Pectoris—Levine and his associates performed partial or complete removal of the normal thyroid in twelve patients suffering from the most severe forms of heart disease. There were four having angina pectoris, four having valvular heart disease and auricular fibrillation, and four having nonvalvular congestive heart failure. They were all hopeless cardiac cripples and, for the most part bedridden. Improvement in six was marked. In three, it was slight to moderate. In one there was no improvement. In one sufficient time has not elapsed to judge. There was one operative mortality in a patient who was moribund at the time of the operation. The most promising patients at present seem to be those suffering from angina pectoris. This work was a direct and logical sequel of the clinical experience in the care of ordinary thyrocardiac patients. The results were sufficiently beneficial to warrant the conclusion that this new procedure will prove helpful in the treatment of properly selected patients suffering from various forms of heart disease who do not improve under the measures customarily used.

Treatment of Typhoid—Lantin and Guerrero employed transfusion after partial exsanguination in seven and transfusion only in three cases of typhoid positively diagnosed by blood

culture. Eight of the ten patients treated made a complete recovery. Another patient is on the road to convalescence. The other patient died, but in the opinion of the authors this was in no way attributable to the treatment. Despite the unfavorable prognosis indicated by late blood cultures in some of the cases, the toxic symptoms improved and gradually subsided after treatment until complete recovery was obtained. In the cases with moderate intestinal hemorrhages, in which transfusion without exsanguination was performed recovery was obtained.

Treatment of Juvenile Dementia Paralytica—Potter treated thirty-eight cases of juvenile dementia paralytica with malaria or tryparsamide or both, twenty with common arsenicals and bismuth or mercury compounds and two with radiotherapy and diathermy respectively. Of the twenty patients who were treated with common arsenicals, seventeen continued to undergo a mental and physical deterioration and several of these died. In twenty-seven of the thirty-eight treated with malaria or tryparsamide the treatment was effective in that it prevented further deterioration, five gained a complete remission and nine a partial remission. The observations as to the effect of treatment were made at least one year after treatment was instituted and, in the majority of instances, a period of from two to five years. In studying the factors that affected the prognosis in the thirty-eight patients treated with malaria or tryparsamide the author found that the prognosis is better in (1) patients who prior to the onset of the dementia paralytica were of normal mental level, (2) patients who were in or past adolescence when the symptoms developed, (3) patients showing the expansive and confused reaction types and (4) patients in whom the elapsed time between the onset of the disease and the treatment did not exceed two years. Sex, character of the onset and antisyphilitic treatment prior to the onset did not appear to affect the prognosis.

Simple Test of Renal Efficiency—M. Clure and Stewart recommend the following test for the study of the excretion of any chosen material in functional irregularities of the kidney (total solids, electrolytes, urea, hydrogen ions, chloride), but for simplicity the total solids as measured by specific gravity, may best be taken. Without heavy supper drinking the patient is asked to empty the bladder at bedtime and again on waking. The latter specimen is collected. He is to note both times exactly. Thereafter, the patient taking no fluid on waking and taking a light dry breakfast, urine is to be collected at intervals of from fifteen to sixty minutes depending on the rate of secretion. Two hours after breakfast he is to drink from $1\frac{1}{2}$ to 2 pints of water and the collection of samples of urine is continued until the height of the diuresis is past the time of each micturition being noted. By such means, samples varying greatly in minute volume can be taken within a relatively short time from normal persons. The only measurements to be made on these are the volume and the specific gravity, and the data are examined by means of a graph, the logarithm of the specific gravity being plotted against the logarithm of the volume per minute. Only the last two figures of the specific gravity readings are taken into account.

*Effect of Radical Antral Surgery on Bronchitic Asthma W. P. Warner and C. McGregor — p. 595

Effect of Surgery on Bronchitic Asthma—Warner and McGregor selected thirty-one asthmatic patients for radical antral operation. In removal of the thickened mucoperiosteum local anesthesia was used in nearly all the cases. The canine fossa was exposed by a horizontal incision just above the gum margin and an opening was made in the anterior wall of the antrum. The mucoperiosteum was stripped from the bony wall by a periosteal elevator and completely removed. An intranasal opening was made in the inferior meatus. This opening extended as high as the attachment of the inferior turbinate and was made as close as possible to the floor of the nose. It extended anteriorly to the posterior surface of the ascending process of the superior maxilla and posteriorly from one-half to two-thirds the length of the nasal wall of the antrum. In some cases a flap of nasal mucous membrane was turned into the antrum. When the inferior turbinate seemed to obstruct the antranasal opening, either the anterior end was removed or that portion opposite the opening. No ethmoidal work was done, as this could be dealt with later if necessary. The patients were observed closely for from six months to two and a half years, and in only two cases were the results decidedly favor-

able and permanent to date. All patients had a period of freedom from asthma following the operation but relapsed later. The longest period was twenty-seven months, the shortest two weeks, and the average of all cases four months. The patients apparently benefited had had asthma for a relatively short time and presented markedly thickened mucoperiosteum. The authors treated five patients having chronic bronchitis by radical removal of the thickened mucoperiosteum and observed them for a period of two years. No benefit was seen to be obtained as a result of the operation.

Peptone Culture Medium—According to Wright, the difficulty in preparing a broth suitable for the cultivation of pneumococci is largely due to the incomplete reduction of peptone. This may readily be overcome by adding peptone to the broth before any heat is applied and so exposing it to the powerful reducing action of meat or meat infusion during the steaming process. Hinton's method of preparing broth owes its advantages to the fact that it provides for adequate reduction of the peptone. Other features in this method, especially filtration through glass wool, have been found to be of minor importance. The presence of oxidized peptone in broth renders it relatively unsuitable for the cultivation of many aerobes and for *Clostridium tetani*. This inhibitory effect must be taken into account in experiments relating to accessory growth factors and oxidation-reduction potential.

Antianemic Principles in Stomach and Liver—Wilkinson and Klein describe experiments that confirm previous evidence that the antianemic principles in hog's stomach and in liver are not identical, and that the active principle of the stomach, hemato-poietin, acting on some substance present in protein food, produces a hematopoietically active thermostable substance similar to or identical with the active principle of

the liver. They review the evidence that hemitopoietin is much more unstable than the active intranemic principle in liver and has different properties from it. When stomach fractions containing the thermolabile hemitopoietin are incubated with beef or gastric muscle, hemitopoietically active material is obtained which is relatively heat resistant. These experiments are considered to effect *in vitro* the synthesis of a substance similar to or identical with the active principle of the liver. It is therefore considered that the enzyme hemitopoietin by acting on some substance present in protein food—e. g., beef—may produce *in vivo* a substance which is stored as the active principle found in liver until it is required for the formation of red cells. Hemitopoietin is present in the normal stomachs of man, carnivorous animals and omnivorous animals but has not been found in the stomachs of herbivorous animals. The available evidence goes to show that true pernicious anemia is a type of deficiency disease characterized by the absence from the gastric secretion of a specific enzyme hemitopoietin, in addition to the pepsin and hydrochloric acid. The authors' evidence for the enzyme nature of hemitopoietin is based on (1) experiments with gastric juice, (2) incubation experiments involving the action of the thermolabile hemitopoietin on an extrinsic substrate (beef or stomach muscle) giving a relatively heat resistant product similar to or identical with the active principle of the liver, (3) the invariable association of pernicious anemia with deficient secretion of enzyme, (4) the difficulty of extracting hemitopoietin from gastric tissue, (5) its apparent destruction by the prolonged action of pepsin and trypsin, (6) its association with the protein fraction of gastric press juice, (7) its instability and (8) its sensitiveness to chemical treatment and heat.

Cancer of Larynx.—To overcome the difficulty of fixation of the needles, Asherson found anchorage by means of a catgut templet and a silkworm gut tension suture of value. The templet is a loosely woven mesh of seven dry absorbable catgut. The radium needles transfix it, in a close palisade, in the way that pins are stacked in rows on paper. Before operation the sterilized threaded radium needles are fixed to the strip by transfixion. The needles are stacked close together, in parallel palisade formation. When the bed for the radium needles has been exposed by resection of part of the hyoid and thyroid cartilages—e. g., for carcinoma of the epiglottis—a loaded strip is cut and trimmed to correspond to the size of the bed. The templet is lowered into position and the skin sutured over it. There is no difficulty in recovering the radium at the end of seven days, as the catgut mesh has disintegrated by then. In anchorage by means of a silkworm gut tension suture the needles can be retained indefinitely in place by being strung on and suspended from a fixed nonabsorbable suture. A strong silkworm gut is passed through the eyes of the threaded radium needles, which are drawn together snugly and parallel with one another. To each free end of the silkworm-gut is threaded a curved, cutting-edge needle. The serried palisade of radium needles is placed in the operative bed formed for it after resection of the cartilage. The adjacent attached needle transfixes the tissues, from within outward, at the upper, anterior, deepest part of the radium bed, taking up sufficient tissue to ensure a firm anchorage. The needle further transfixes all the tissues, emerging through the skin at some distance from the margin of the incision. An artery forceps is attached to the free end of the silkworm gut after the needle has been detached. The other end is similarly drawn through the upper posterior and deepest part of the radium bed and then through the skin and an artery forceps attached to it. The first point of entry of the needle on each side is such that traction simultaneously exerted on both ends of the silkworm gut will draw the embedded silkworm gut line taut and so draw the radium needles into position firmly, retaining them in place. After the skin incision has been sutured, the free ends of the silkworm-gut are tied together firmly over it. It forms a tension suture and may be tied over a small pad of gauze to act as a dressing stay suture obviating the use of a pressure bandage. To withdraw the radium, the silkworm suture is severed on each side close to the skin. It has been the author's custom when embedding radium to twist all the attached double threads into one cable knot this about 3 inches from the needles cut the

redundant ends short and coil the cable up in the depth of the wound at its lower part. The wound is then completely sutured. When the wound is reopened, the edges are gently prized apart with dressing forceps and the cable is easily picked up. Even if only a single thread is located, traction on it will withdraw the entire bundle. Extraction of the needles may be facilitated by previously tying a single withdrawal thread around the cable and allowing it to come through the lower end of the incision. The author believes that fixation by the stay nonabsorbable suture is the method of choice, as it is rapidly performed and there is no occasion to excise a window from the cartilage to fit the exact length of the radium needles available.

Cancer Treated with Connective Tissue Extracts.—Baker outlines a method of treatment which has given encouraging results in thirteen cases of inoperable cancer. He is of the opinion that the excessive growth of cells is controlled by substances secreted in the connective tissue of their area. It is not an unreasonable postulate that a factor exists to inhibit the tendency of living cells to reproduce themselves indefinitely and his work is based on the view that this factor is a substance secreted locally outside the blood stream and discharged into the lymph. If a cell, or group of cells, is deprived of adequate inhibition—e. g., by lymph stasis or actual failure of secretion—it will reassert its fundamental tendency toward unlimited growth. It is not impossible that the inhibitory factor is an enzyme and for various reasons it is considered that its major function is lipolytic. It is secreted in the connective tissues and functions to the best advantage in the area of its secretion. In normal healthy persons it is destroyed in the lymph nodes and eventually, if it escapes this, in the blood stream. Treatment is designed to introduce this essential substance into the carcinoma by the intravenous administration of an extract of connective tissue derived from an area, in the pig or cow, corresponding to that of the primary growth in the patient. The author's experience with this treatment has been that the patient loses his cachectic appearance and the carcinoma diminishes in size and becomes attenuated in vigor. This suggests that by repeated courses of treatment at lengthening intervals the carcinoma may be deprived of its power to destroy life. Assuming that the inhibitory factor has been introduced in the blood stream in sufficient quantity and is circulating, it is manifest that it will attack the overgrowth of cells, at any rate cells from its own area, wherever it may meet them. That is to say, its action can be expected to, and in fact does apply to metastases as well as to the primary growth. The preliminary dose was in every case 1 cc. Subsequent doses were increased gradually with a view of overcoming a postulated increasing resistance of the blood to inhibition. The maximal dose was 25 cc. The author thinks that the method of choice is without doubt the intravenous route and that the interval between doses to secure a proper clinical effect should not exceed four days. The immediate result of the injection is flushing of the skin around the area of injection. This is followed by flushing of the face suffusion of the conjunctivae and discomfort—sometimes amounting to pain—in the tongue, within about thirty seconds. If large doses are given these symptoms are followed by a throbbing headache, which may last for half an hour. Rigors occurred in one case.

Alleged Cancer-Producing Qualities of Tomatoes.—Des Ligneris negates Askanazy and Bellows successful production of peritoneal sarcoma in rats by means of injections of

tomato juice Neither in rats nor in mice did a single case of sarcoma occur, nor did the subcutaneous or intracutaneous injections of tomato juice into mice when added to tarring hasten the formation of skin tumors The author's results have been confirmed by Collier and Jaffe Lischl and Kussat Iriomow Pawlowa and Schabard The negative results as well as the positive results of Bellows and Askuray suggest that the presence or absence of an inherent constitutional factor in the experimental animals is of paramount importance If this factor is present it is easy enough to produce true tumors by means of any chronic irritation of adequate severity and duration but if this factor is absent unspecific irritations like the irritation caused by injections of tomato juice elicit no true neoplastic response

Treatment of Pulmonary Tuberculosis by Gold—Cruden began to give gold injections to fifty tuberculous patients because large amounts of sputum remained tubercle bacillus positive for failure to improve or insufficient improvement under ordinary sanatorium regimen or because of an acute spread of the disease If albuminuria was absent the intravenous injections were commenced The first dose given was usually $\frac{1}{40}$ gram and the injections were continued at weekly intervals unless complications ensued The usual course consisted of two injections each of $\frac{1}{40}$ $\frac{1}{20}$ $\frac{1}{10}$ $\frac{1}{5}$ $\frac{1}{2}$ $\frac{1}{4}$ and 1 gram (0.002 0.003 0.006 0.016 0.032 0.05 and 0.065 Gm. respectively) of Sincrysin and a double thiosulphate of gold and sodium (Crystalline) Ten of the patients received Sincrysin and thirty eight double thiosulphate of gold and sodium The remaining two were given a proprietary gold preparation used for epilepsy (Solgarin) in total doses of $1\frac{1}{2}$ and $1\frac{1}{10}$ gram (0.12 and 0.123 Gm.) respectively The results confirm the generally accepted view that gold treatment has at any rate a temporarily beneficial effect in selected cases of pulmonary tuberculosis being especially useful in rendering the sputum tubercle bacillus negative and diminishing its amount There appears to be a simultaneous improvement in the general condition of the patient The psychologic effect on certain patients of a form of treatment additional to the ordinary sanatorium regimen is quite convincing and is of definite benefit to the patient The fact that complications (of a mild nature) occurred in 70 per cent of patients shows the necessity for close supervision Urinary complications (hematuria, mild albuminuria and jaundice) were frequent All trace of icterus disappeared within five weeks of the onset after the administration of dextrose and purified sodium thiosulphate The two patients receiving the proprietary gold preparation experienced nausea vomiting and syncope The patients soon recovered from these complications and appeared to have benefited from the course as evidenced by their general improvement and the disappearance of bacilli from the sputum

Carbon Monoxide Intoxication—Balthazard and Melissinos state that the variations of the coefficient of intoxication in carbon monoxide poisoning are due to physiologic causes and do not impair the theory which attributes death in carbon monoxide poisoning to anoxemia They found that in all cases in which the value of the coefficient was between 0.42 and 0.8 the carbon monoxide was if not the sole at least the principal cause of death This is not the case if the coefficient has a value of less than 0.42, which is plausible only in cases in which the period of survival is more or less prolonged Coefficients of 0.05 or less, regarded by some authors as a sign of carbon monoxide poisoning denote on the contrary, that death is due to some other cause The organism can withstand without inconvenience doses of carbon monoxide corresponding to coefficients of 0.1 0.2 and even 0.3 Such values might be observed in persons remaining near a fireplace or a poorly installed heating plant without any experience or discomfort on their part If these persons are found dead their death must be attributed to some other cause than carbon monoxide poisoning The finding of values below 0.42 in manifest cases of carbon monoxide poisoning may be due to technical errors in determination of the coefficient or to putrefaction of the reduced hemoglobin (with preservation of that combined with carbon monoxide) in cases in which examination is made long after death The authors demonstrated experimentally that reduction of the oxygen content in the atmosphere lowers the coefficient of carbon monoxide intoxication and inversely increase of the oxygen content raise the coefficient They consider the administration of pure oxygen, preferably under pressure, the only rational and efficacious therapy in carbon monoxide poisoning

Presse Medicale, Paris

11 1901 1924 (Nov 23) 1933

- Treatment of Arterial Hypertension by Intravenous Injections of Octyl Alcohol A Clerc J Sterne and R Paris—p 1901
- Mortality in 120 000 Spinal Anesthetics C Angelesco and S Tronaru—p 1904
- Prevention of Serum Accidents by Ingestion of Ephedrine and Its Regular Renewal I P Levy—p 1906

Treatment of Arterial Hypertension—Clerc and his associates report that in ten of eighteen patients intravenous injections of octyl alcohol in a weak aqueous solution produced a progressive and sometimes lasting reduction of arterial hypertension The octyl alcohol also exerted a diuretic and a general sedative action to a degree not observed with other hypotensive agents They employed the alcohol rigorously purified obtained by redistillation in a 1 100 000 dilution with distilled water The series of intravenous injections was started with a dose of 10 cc later increased to from 15 to 20 cc and repeated every other day The series averaged from twelve to fifteen injection, but in some cases as many as eighteen were given The diuresis observed even in patients in whom the arterial tension was not decreased (sixteen out of eighteen) and the sedation of functional disturbances (observed in fifteen patients) usually became manifest between the third and fifth injections The lowering of the arterial tension usually appeared toward the eighth or tenth injection progressing gradually but never descending below normal A relative lowering of the surface tension of the blood was observed No strict parallelism between the various phenomena produced by the injections was observed In some cases the duration of the hypotensive effect lasted only a few weeks in others several months and in one case six months Repetition of the series of injections after an interval of several weeks produced in some cases the renewal and in others the accentuation of the favorable effects The injections are not attended by any undesirable effects and there are no contraindications to their use While the individual response to the treatment is variable the most favorable cases are those presenting the least cardiorenal involvement The authors think that this

therapy while not miraculous or constant in its effects merits the attention of clinicians

Prevention of Serum Accidents by Ephedrine—In view of the constantly increasing frequency of serum disease Leva recommends the ingestion of ephedrine before the injection of serum and at regular intervals afterward for the prevention of serum accidents. He considers it superior to epinephrine because it is efficacious when ingested and its action is slower, more gentle and more lasting. The first tablet of ephedrine is ingested one hour before the injection of the serum and thereafter a tablet is taken every eight hours (even during the night) for fourteen days. For children aged from 1 to 4 tablets of 0.01 Gm are used, for children aged from 4 to 9, tablets of 0.02 Gm and for patients of more than 9 years tablets of 0.03 Gm. In a grave case of diphtheria in which a delay of one hour before serum injection is considered dangerous, a solution of ephedrine containing the equivalent of the tablet may be injected parenterally twenty minutes before the serum injection. The author employed this method of prophylaxis in a number of patients ranging in age from 18 months to 55 years, who received intramuscular or subcutaneous injections of nonpurified antidiphtheritic serum in doses varying from 10 to 500 cc spread over several days. Among seventy-eight children receiving this treatment five experienced marked reactions with strong or average eruptions and general symptoms, while fourteen had only slight eruptions without general symptoms and fifty-nine had no reaction at all. Among thirty-nine adults receiving the same treatment eight experienced strong reactions while thirty-one experienced no reaction or only slight cutaneous eruptions without general symptoms.

Chronic Abdominal Splanchnopathy and Diabetes Mellitus—Cannavo describes a form of diabetes mellitus secondary to chronic abdominal splanchnopathy which he found in a number of patients at an earlier age than that of hypertonic diabetes, the diabetic symptoms beginning between 30 and 40. It is not accompanied by arterial hypertension and is a genuine pancreatic diabetes. In the beginning period it shows a notable diminution of external pancreatic secretion. It occurs in patients presenting a long history of dyspeptic symptoms, resulting from chronic appendicitis, cholecystitis or peptic ulcer. The development of diabetic symptoms is always preceded and accompanied by classic pancreatic symptoms. Roentgenologic examination generally reveals enlargement of the pancreas and marked changes in form of the serous membrane that surrounds and envelops it. Histologic examination demonstrates the presence of interstitial pancreatitis with lesions of the secretory cells of the pancreas. Hereditary diabetes and etiologic factors such as syphilis, malaria typhus and epidemic parotitis, which often influence the genesis of true diabetes were not present in this form of the disease.

Treatment of Fractures—Magnus states that 4518 cases of fractures were treated in one year at the Hospital for Miners at Bochum. His conclusions are based on experience derived

from eight years of service at this institution. Between 1925 and 1930 there were treated 3,432 fractures of the long bones. Of these, 102 (3 per cent) were treated by the open method of reduction, while 3,330 were treated by the conservative method of closed manual reduction. The operative method was resorted to only when the conservative method proved ineffective. The average time chosen for operative intervention was the twelfth day. The indications for surgical intervention were failure to accomplish correct anatomic apposition of fragments, inability to maintain the reduction and failure of bony union. Interposition of the soft parts was the principal cause of failure of reduction. The author has adopted the principle of not leaving any foreign fixation material in the wound but of relying instead on purely osteosynthetic methods of maintaining reduction principally on the autoplasmic bone transplant. Duration of treatment with the open method was longer than with the closed method. The average time in the case of a fracture of the forearm between the operation and consolidation of the bone was forty-four days, and between operation and return to work seventy-eight days. The author resorted to wire suture of the fragments in twenty-six instances. In his method the wire is introduced subcutaneously and is tied on the skin. The suture is easily removed after the fracture is consolidated. The results with this method were not always satisfactory. In sixteen cases of fractures of the forearm it gave ten excellent, four satisfactory and two poor results. The average duration of treatment was 122 days. Percutaneous nailing has a narrow field of application and was resorted to in only three instances. In recent years the author resorted more and more to the method of free bone transplant whenever compelled to operate. This method was particularly successful in fractures of the forearm. It gave an excellent result in eleven out of twelve cases, and a pseudarthrosis in one. There were thirty-one instances of pseudarthrosis among 1,602 fractures. One of the reasons for the relatively frequent pseudarthrosis in the material was the fact that fractures occurring in miners are the result of severe trauma accompanied by extensive tissue necrosis. The author is enthusiastic about the method of bone fixation with a free bone transplant. The process of bone healing was little, if at all, influenced by the various calcium preparations, by viosterol and by injections into the seat of the fracture. The success of operative reduction depended on the completeness of reduction and a sufficiently long and efficient fixation. Of 428 cases of fracture of the radius, only 6 were subjected to an open operation, in the rest, manual closed reduction was carried out under general anesthesia. While local infiltration anesthesia permits of easy reduction, preference is given to general anesthesia for purely psychic and humane reasons. The severity of the fractures of the tibia is attested by the fact that, out of 813 cases, 63 came to amputation. The skeletal method of traction has been substituted for all other methods, not only in fractures of the lower extremities of adults but in fractures of the upper extremities and in children as well. Long continued traction is indicated in the type of fracture that is likely to lead to shortening of the limb. Control roentgen examinations by means of a portable apparatus without disturbing the fracture are a great aid in the treatment. The final results are judged on the basis of shortening of the limb and the function of the joint. Vertebral fractures not complicated by injury to the spinal cord were treated by the purely functional method, that is without an attempt to reduce the fracture or to fix the spine in a plaster cast. Impaction was considered a favorable element and no attempt was made to reduce it. Fractures of the clavicle fall into the same category of functional treatment. No attempts were made at reduction or fixation, and treatment was limited to massage and motion.

Operative Shock—Rehn stresses the necessity for the employment of scientific methods in determining the character of postoperative circulatory disturbances and the origin and development of operative shock. Methods reflecting the momentary condition of the circulation rather than its functional capacity are of no value. This can be said particularly of the most frequently resorted to method of measuring the peripheral blood pressure. It does not reflect the true condition of the circulation even when combined with determinations

of pulse frequency and amplitude. Electrocardiographic studies disclose disturbances of rhythm and the condition of the heart muscle, but not the functional capacity of the heart. Methods capable of determining the quantitative hemodynamics are the only ones free from objection. These methods give, in minute volume, information regarding the peripheral circulating blood volume and the condition of the heart as well. It is in combination with this method that the measuring of blood pressure and the study of the pulse acquire an importance in the estimation of the true condition of the circulation. When performed by a well trained investigator, the method is absolutely reliable as well as harmless even to the sick. If an operation is to be regarded as an equivalent of physical exertion, a normal person with a normal heart should respond to it with an increase in the minute volume. Such was found to be the fact. Diminution in the volume of the circulating blood signifies a state of depression. The rise in the minute volume is an expression of a successful attempt at compensation. Shock will develop if the volume of the circulating blood continues to fall so that the blood supply to the heart becomes insufficient in spite of the increase in pulse frequency. A damaged heart may fail to meet the increased demands made on it. In either instance a diminution in the minute volume is demonstrable. It is synonymous with shock. A fatal outcome as a direct result of operative shock has become much less frequent than was formerly the case. The disturbances described require a great importance, however, because of certain secondary effects on the composition of the blood and the central nervous system, which may bring about fatal collapse. Less direct consequences are encountered after a free interval in the form of thrombosis, embolism, pneumonia and late collapse.

Treatment of Vertebral Fractures—Böhler believes that vertebral fractures should be treated as any other fracture by reduction of fragments and fixation. His views were opposed by all discussers at the last meeting of the Congress of German Surgeons. The method, however, was used in England and in the United States of America for years. Since 1930 the author began to treat his patients, after the reduction of fracture and fixation in a plaster jacket, by putting them through systematic exercises. Disability after a vertebral fracture when injury to the cord and injury from subluxation are discarded is in a direct relation to the degree of distortion of the vertebral column. Vertebral fractures accompanied by distortion of the vertebral axis lead to permanent disability because the static conditions are changed and because still further distortion of the column will cause displacement of the thoracic and abdominal viscera. No injury to the spinal cord will take place if the reduction is accomplished with the aid of local anesthesia, the extension in suspension taking from fifteen to twenty five minutes until the gibbosity disappears and a marked lordosis becomes evident. One is certainly obliged to reduce the fracture in the presence of paralytic symptoms. Laminectomy becomes necessary in a few cases in which reduction cannot be accomplished by extension. This is the case when the articular processes are dislocated but not fractured. When a patient is put to bed in a plaster cast he is rendered both physically and psychically ill. The muscles become weak, the bones lose some of their calcium content and the vertebral joints become stiff. The author's patients are permitted to walk without a cane on the second or third day after the application of the cast. Twice daily the patients are put through exercises of the arms bending of the knees, extension of the legs and muscling up of the body on rings. To strengthen the muscles of the back, the body is made to rise from a horizontal to a vertical position. Lifting of the thighs while lying flat on the back develops particularly the ileopsoas muscle, which bears the closest relationship to the fractured vertebrae. Toward the end of the treatment the patients are made to carry a weight on their heads for from twenty to forty minutes. They begin with a weight of from 1 to 2 Kg., which is increased to 50 Kg. Patients treated in this manner are in the best physical and mental condition. Eighteen patients treated on this regimen gave excellent results. Of these seven had fractures of cervical, four of thoracic and seven of lumbar vertebrae. They were able to resume heavy work in from four to seven months. Not one was receiving compensation one and a half years later.

Localization of Bacteria in Bones—Schulze states that the tendency of bacteria to localize in the metaphysis of the bone in hematogenous infections is due to the peculiar structure of its blood vessels. This refers not only to the arterial distribution but to the form of the capillaries as well. The roentgenologic and histologic pictures of experimental bone tuberculosis in rabbits bears a marked resemblance to that of certain forms of human bone tuberculosis and congenital syphilis of the bone. The conclusion is drawn that the special forms of bone disease observed in human beings are likewise conditioned by the character of the blood supply. Anastomosing arterial branches that pierce the epiphysis are found in the area between the epiphysis and metaphysis of the tubular bones in man and in many animals. They can be demonstrated even before the ossification is completed. Such perforating branches do not exist in dogs. Injection of small amounts of India ink in Ringer's solution into the femoral artery of young dogs caused cone-shaped areas of disturbed growth. This was caused by embolic blocking of a branch of the nutritive artery running toward the metaphysis. These localized areas of disturbances of growth furnish additional proof of the fact that the large nutritive branches running to the metaphysis are terminal arteries.

Rectum and Genito Urinary Organs in Lymphogranuloma Inguinale—Gohrbandt says that lymphogranuloma inguinale has so far been considered a venereal disease unrelated to syphilis, gonorrhea, tuberculosis, carcinoma, soft chancre, or ordinary infection. Diagnosis in the early cases is easy but in the advanced case may be difficult. Frei's skin reaction when positive is of the greatest importance in diagnosis. The spread of the lesion in men and in women is different because of the difference in the distribution of the lymph nodes and lymph vessels. In women, the lymph nodes involved are those of the introitus and of the perineum, and the perirectal and the iliac nodes, in men, the perirectal and the deep nodes of the pelvis. The disease in women manifests itself in the beginning as an edematous, frequently elephantiasis-like swelling of the external genitalia, principally of the labia associated with a more or less pronounced ulceration. The involvement of the rectum is of interest to the surgeon. The author has seen fifteen such cases in the last two years, twelve in men and three in women. The superficial nodes perforate on the skin and the deep nodes into the rectum. The latter event leads to an aggravation of the condition because of a mixed infection. The author has seen as many as twelve fistulas opening into the rectum. This condition is accompanied by high fever. Scar formation leads to the gravest forms of stricture of the rectum. With regard to therapy, he states that the milder cases are amenable to treatment with the heavy metals, in particular with gold preparations. He obtained good results with a gold preparation ("Solganal") introduced by Naumann of Hürt. Careful passage of sounds and irrigations are helpful. In the more severe cases the creation of an artificial anus becomes necessary. Extirpation of the rectum is likely to prove fatal to patients, who are usually in bad condition.

Surgical Treatment of Uremic States—Rieder reports a case diagnosed by internists as one of malignant nephrosclerosis, in which he denervated one kidney. Subsequent studies showed that the urinary output by the denervated kidney increased from three to five times. Increase in the absolute values of urine-forming substances was recorded in the presence of diminished concentration of the urine from that side. All uremic symptoms disappeared. The blood pressure fell from 200 to 140/90. The patient was exhibited at the Congress of Surgeons nine months later in perfect health and restored to full working capacity. The author warns against indiscriminate denervation in every case of malignant nephrosclerosis or glomerulonephritis. Functional improvement may be expected in those cases only in which the disease depends primarily on the existence of spastic states. It is not possible to recognize these cases with any degree of certainty, because no knowledge exists as to the cause of nephrosclerosis and glomerulonephritis or as to the time of onset and existence of these vegetative disturbances. His operative results would suggest that the progression in such cases depended on spasmodic states. Operation is

of no value when the process has advanced so far as to be irreversible. The indications for denervation must be strictly limited. The problem is to select a suitable case. The happy outcome in the author's case suggests that there exist certain forms of beginning uremia in which denervation of a kidney results in considerable improvement. He calls attention to two cases of glomerulonephritis of mild severity which showed no tendency to healing and which responded favorably to the denervation operation. In the more severe cases of uremia the operation is almost certain to precipitate a state of acidosis with a fatal outcome. To obtain a favorable result it is necessary to resect all the nerve fibers running along the anterior and the posterior aspects of the renal artery from its origin at the aorta to the renal hilus. An exact knowledge of the rich nerve plexuses about the kidney as well as of their origins is essential to successful operation.

Influence of Biopsy on Prognosis of Cancer of Breast

—Siemens calls attention to the experimental work of Francis Wood, in which the latter inoculated 400 rats with Flexner's carcinoma. A biopsy was performed in half of the animals. The tumor was removed in all. Several months later the animals were killed. Necropsies showed that the animals on which biopsy was performed did not develop more pulmonary metastases than the control group. The comparative figures presented by the author to show the influence of a biopsy on the subsequent course of cancer of the breast include only those cases in which a radical operation and subsequent irradiation were carried out. It is generally agreed that the operation must follow shortly on the histologic diagnosis. From 1913 to 1929, 309 cases of carcinoma of the breast were treated surgically at the University of Kiel. Diagnosis of carcinoma from biopsy was made in 59. The tissue was removed with a scalpel. The axillary lymph nodes were found enlarged on palpation in all but 9 of these cases. No histologic proof of metastatic invasion of axillary lymph nodes was found in 28 cases (47.9 per cent). All 28 patients survived the five year limit. These results suggest that extension of carcinoma cells did not take place between the time of the biopsy and the time of the operation. In the remaining 31 patients the glands were found to have undergone malignant degeneration. Of these 10 died before reaching the three year limit, 9 died between the three and five year limit, and 4 died between the five and ten year limit. The better results in the biopsy group were undoubtedly due to the fact that they were earlier cases. However, the author feels justified in concluding that the biopsy did not aggravate the morbid process, did not accelerate the growth of the neoplasm and did not stimulate the formation of metastases. Even the group with palpable carcinomatous lymph nodes, in whom a biopsy was made, showed a 10 per cent improvement in the results for the three and five year periods and a 21 per cent improvement for the ten year period, when compared with the group in which biopsy was not made. Biopsy was made in six inoperable cases. Five of these patients died within the next two years, and one was alive seven years later. Apparently there was no untoward effect in this group as well. In performing the biopsy the entire growth must be widely excised. The "rapid method" followed immediately by the radical operation is to be recommended. In sixteen cases in which this method was carried out, the results compare favorably with other groups. Of these patients, 81 per cent survived the three year period and 69 per cent survived the five year period.

Surgical Treatment of Angina Pectoris—Braeucker obtained excellent results in five cases of angina pectoris by operative intervention. In the first case severe attacks of angina pectoris, the result of coronary sclerosis and aneurysm of the heart, disappeared after the section of communicating branches on the left side from the fifth cervical down to and including the first thoracic. The patient was symptom free three years later. The second case was one of severe angina pectoris resulting from syphilitic aortitis. The patient was still symptom free two years after a left-sided ramisection (from the fifth cervical to the first thoracic) and extirpation of the inferior cervical and the two upper thoracic ganglions. In the third case, complicated by syphilitic aortitis and aortic insufficiency, the patient was symptom free one and a half

years after the extirpation of the inferior cervical and the two upper thoracic ganglions. The fourth patient was symptom free three years after a bilateral ganglionectomy, and the fifth, two years and eight months after a left cervical ganglionectomy. The author believes that noxious irritants proceeding from a cardiac or aortic lesion set up an irritation in the ganglions, the regional centers of the cardiac plexuses. The ganglions respond by creating a return vasoconstricting reflex with resulting ischemia of the cardiac musculature, the probable cause of an attack of angina pectoris. In the absence of a cardiac or aortic lesion, the attacks may be provoked by abnormal irritation of the extracardiac nervous elements. This type, in which no organic lesion is demonstrable, is termed vasomotor angina pectoris. The lower cervical and the upper thoracic ganglions play an important part in the painful syndrome because most of the centripetally running cardiac and aortic impulses must pass through them. The good result after ramisection is explained by the hypothesis that it allays the irritability of the ganglion. The author, while operating on the neck under a local anesthetic, made an observation previously recorded by Leriche, that the stimulation of the stellate ganglion provoked a typical anginal attack and that injection of procaine hydrochloride into it stopped the attack. The same observation was made when the first thoracic ganglion was electrically stimulated. These ganglions receive impulses proceeding from the heart, which are then relayed as vasoconstrictors to the periphery. The automatic capacity for generating reflex impulses is retained by these ganglions even after their severance from the spinal cord by sectioning of the communicating branches. This explains why better and more permanent results are obtained by ganglionectomy than by mere sectioning of the communicating branches. The idea that the stellate ganglion plays an important part in the regulation of cardiac activity loses its validity when the ganglion becomes the seat of pathologic reflexes. The author concludes that bilateral extirpation of the inferior cervical and of the two upper thoracic ganglions is the operation of choice for the relief of angina pectoris.

Babinski's Sign—Sehestedt points out that when Babinski first described the extension reflex of the great toe as an indication of a lesion of the pyramidal tract he also noted that this reflex is nearly always present in healthy nurslings. Many explanations have been attempted but an entirely satisfactory explanation for the presence of the reflex in nurslings and its disappearance in older children has not been given as yet. Some authors explain its presence in nurslings through the incompleteness of the pyramidal tracts. Others reject the equation of the extension reflex in nurslings and adults and its relation to lesions of the pyramidal tract and consider it an athetotic movement due to an insufficiency of the pallidal system. Others (particularly Zador) found that not all lesions of the pyramidal tract are accompanied by the sign, while the sign may appear in the absence of such lesions, and they assume that influences of the pallidal system are involved. Numerous other students have pointed out that the change in this reflex takes place during the period when the nursling learns to stand and walk and they conclude that the presence of the extension reflex in children who can stand and walk is pathologic, except that during the transitional period an acute disease may cause a relapse. Since on the basis of this theory, it was reasonable to assume that older children who do not walk for longer periods would lose the flexion reflex and would reassume the extension reflex, the author studied Babinski's reflex on sixty-two children aged from 6 to 15 years, who had been bedridden for months or years. His observations corroborate the theory that Babinski's sign is the original reflex of the sole of the

foot and that the flexion reflex is a conditioned reflex, the result of static conditions and lost by lack of exercise. This makes it unlikely that the extension reflex in nurslings is the result of the incomplete development of the pyramidal tracts, as has been assumed by some investigators. The author is inclined to agree with Zador that between the Babinski extension reflex in nurslings and the form that occurs in adults there are probably close connections.

Muscular Tension in Chorea Minor—Reisch was able to study the conditions under which increased muscular tension develops, in a patient in whom the tension phenomenon persisted for months after the disappearance of the choreic restlessness. In order to explain the concurrence of reduced resistance in passive movements and of increased tension of the musculature produced by reflex action he calls attention to similar observations in other extrapyramidal syndromes reports of which are to be found in the literature.

Blood Transfusion in Malignant Diphtheria—Encouraged by the favorable reports of blood transfusion in malignant diphtheria, Dimmel tried this method in sixteen cases in children ranging from 2 to 13 years. The quantities of transfused blood averaged 200 cc. The mortality rate was 35 per cent and, compared with another group of cases of malignant diphtheria in which blood transfusion had not been employed and in which the mortality was 66 per cent this mortality rate was rather low. However, since the cases were comparatively few, the percentages are of slight significance since a single case will make a great percental difference. But aside from the criterion of the mortality rate, the great change that was effected in the general condition and the rapid disappearance of the toxic symptoms indicate the effectiveness of the transfusion. The author is unable to answer definitely the question as to how the blood transfusion exerts its influence whether the antitoxin content of the transfused blood plays a part or the infusion of the blood as such, irrespective of the antitoxin content, is sufficient, but he observed that a donor's blood which had been given successfully in two cases had in extremely low antitoxin content. Blood transfusion was never the only therapeutic method, but the children also received intravenous and intramuscular injections of antitoxin, and circulatory remedies were likewise administered. Since blood transfusion involves little danger and the treatment of malignant diphtheria is still unsatisfactory, the author thinks that blood transfusion should be tried.

Lymphangitis in Connection with Agranulocytosis—Boveri relates the histories of two patients in whom agranulocytosis manifested itself acutely, although the anamneses revealed that disturbances had existed for some time previously. Shortly after the appearance of the agranulocytosis, lymphangitic processes occurred in both cases on the third day of observation. Thus the lymphangitides cannot be considered the causal factors of agranulocytosis but rather the sequelae. Worthy of note are the points of origin of the lymphangitides for in both cases they had existed for some time as harmless surface injuries. In one woman it was a horny growth at the base of the great toe, and in the other woman a slight injury of the finger. Not until the severest stage of agranulocytosis had been reached did these lesions become the starting points of lymphangitides. The question is How did the lymphangitides develop? The author is convinced that they cannot be con-

sidered metastases of a generalized sepsis, but he is inclined to make the complete lack of resistance of the organism and tissues responsible for their development. He assumes that originally apathogenic organisms became pathogenic in that the lowered resistance caused a relative increase in their virulence.

Protracted Fractional and Massive Irradiations—Wintz points out that a review of the literature on the results obtained with Coutard's method of protracted fractional roentgen irradiation of malignant tumors reveals that they are not uniform. Some roentgenologists say that the method is excellent, while others reject it completely. Wintz imitated Coutard's method in the roentgenotherapy of squamous cell carcinoma of the cervix. He considered all factors that influence the applied and the effective doses. The doses were computed as well as determined by measurements on phantoms and human subject. Then the correlation was established between the doses employed in massive irradiation and in Coutard's fractional method and it was found that for the skin the ratio was 1:2, for carcinoma 1:2.4, for the intestine 1:2.2 and for the connective tissue 1:1.4. The doses for carcinoma are so large that they alone explain the destruction of the growth. The author is convinced that the effects obtained with Coutard's method cannot be considered the result of the increased radiosensitivity produced by the distribution of the dose. He maintains that the single irradiation is superior to Coutard's protracted fractional irradiations as regards the efficacy of the smallest intervention, as well as biologically, in that the radiosensitivity is more favorable.

Treatment of Genital Carcinoma—The fact that the Zondeks and Hartoch were able to arrest the growth of inoculated carcinomas in white mice by the administration of prolan A and B induced Ernst to try medication with a preparation containing prolan A in several women with inoperable or relapsing carcinomas of the genitalia and in a man with carcinoma of the penis. In addition to the hormone preparation the patients also received irradiations with radium and with roentgen rays. In three cases the effects of the irradiations had already subsided when the hormone therapy was begun so that it was possible to determine the efficacy of the hormone treatment. It was found to be negative in all three. In five cases namely, four genital carcinomas in women, and one carcinoma of the bladder the hormone therapy was accompanied by a loss in weight. But although the administration of the hormone of the anterior hypophysis did not bring the desired results in the treatment of genital carcinoma in women the author emphasizes that the same hormone preparation proved highly effective in ovarian dysfunction particularly in amenorrhea.

Roentgen Therapy of Inflammation of Nail Bed—According to Jessen, the inflammation or suppurative of the nail bed often presents therapeutic difficulties. In surgical treatment, for instance, which formerly was the usual pro-

cedure the patient becomes bedridden and thus incapacitated for several weeks. The author obtained favorable results with roentgen therapy. He was able to cure simple pronychia of the fingers or toes with one or two high voltage roentgen irradiations, the second being given ten days after the first. The dose was 30 per cent of the unit skin dose and a 4 mm aluminum filter was used. In the more severe forms of ingrown toe nails, which generally have existed several weeks before medical aid is asked the nail bed is severely inflamed, red and swollen and the nail is partly loosened by a suppuration underneath it. The loosened portion of the nail is removed if possible, from 4 to 6 mm away from the nail bed. After that, 30 per cent of the unit skin dose is applied and a second irradiation is given two weeks later. The author asserts that all his patients improved rapidly and that not a single one was incapacitated for work.

Bleeding Breast as Precancerous State—According to Philipowicz, histologic studies of bleeding breasts by various investigators reveal the following underlying causes: cystic mastopathy, cystadenoma, cystic papilloma and true carcinoma. He stresses the lack of unanimity in the opinions as to the question of the danger of malignant transformation and as to the proper treatment of these cases. In his own material there were five patients with malignant conditions in eight cases of bleeding breasts. Geographic and racial variations may account for the diversity of opinions on the subject. The author reaches the following conclusions: A small palpable tumor may be widely excised and submitted to a histologic study. In the absence of a palpable tumor the patient is to be kept under observation. When, however, this is not feasible and the patient is past 40, a radical operation should be performed. The author is opposed to compromise in the matter of treatment for the reason that the radical operation is no more deforming or dangerous than the mere amputation of the breast. On the other hand the danger of recurrence is real after the conservative method of breast amputation. Biopsy is uncertain and dangerous. There exist social indications for radical operation in these cases, namely, when the patient is not sufficiently intelligent to cooperate and is past 40, and when there is a history of cancer in the family, especially of the breast.

Genesis of Endometriomas—Rieck emphasizes that all studies on the genesis of endometrioma should try to answer the question whether the endometrioma originated in the uterus or not. He accepts Sampson's theory, which gives a misplacement of endometrium as the cause and he formulates the statement that where there is an endometrioma there must be or must have been a functioning endometrium. He asserts that Robert Meyer's theory of the development of endometriomas from the epithelium of the peritoneal serosa has not yet been furnished with conclusive evidence. He sets himself the task to explain the cases which apparently are incompatible

with a uterine origin and which as a result are often explained as originating from the epithelium of the serosa, in the light of the theory of the uterine origin. He cites the case of a woman with endometriosis in whom menstruation was absent but in whom the ovaries functioned normally. Meyer's theory of the development of the endometrioma had been recognized as correct in this case, but on closer investigation an atresia of the body of the uterus was found, and the author thinks that the absence of the menstrual flow in the presence of functioning ovaries, which must have caused endometrial hemorrhages, would explain the endometriosis. He reviews other cases of atresia of the body of the uterus in which menstruation was absent. He considers these cases important in view of the generally accepted rule that operative treatment should be omitted in the absence of menstruation, for in these cases surgical treatment would be helpful. He cites a case treated by him several decades ago. He made a fistula connecting the body of the uterus with the vagina, and the woman had normal menstruation for twenty-five years, but in another case the fistula had closed again and an endometrioma developed. The author concludes that if, in an otherwise healthy, sexually mature girl uterine and peritoneal pains develop periodically without a menstrual hemorrhage and if bimanual examination reveals no other cause for the absence of menstruation, atresia of the body of the uterus may be thought of, and, if probing reveals a uterine canal from 3 to 4 cm in length and the uterus is of normal length, the diagnosis of atresia is almost certain, and the presence of an endometrioma, no matter whether in the umbilical or inguinal regions, makes it still more so. The surgical intervention should be vaginal in cases of this nature.

Modification of Gonads by Hormone of Hypophysis—Fukushima reviews the literature on this subject and finds that some of the reports are contradictory. He was doubtful particularly of the results obtained by Joel and Constantin who observed that the injection of the urine from pregnant women effected an enormous increase (from six to eight times the original volume) in the size of the testicles and of the epididymis. He duplicated their tests and found either an extremely slight increase or none at all. He thinks that the ovarian hormone contained in the urine acted as an antagonist to the hypophyseal hormone. He tested the hypophyseal hormone extracted from the urine of pregnant women and found that the testicles of the animals had become hyperemic and were almost twice their original size. He thinks that this stronger action of the hypophyseal hormone was due to the fact that the inhibiting influence of the ovarian hormone was absent. In order to demonstrate this more conclusively, he heated the urine from pregnant women to the boiling point and then injected it into the test animals. The ovarian hormone is thermostable and consequently unaffected by heating to the boiling point, while the hypophyseal hormone is thermolabile and becomes impaired by a temperature of from 60 to 65 C. The injection of the urine thus treated did not increase the size of the testicles.

Predetermination of Sex in Human Subjects O. Schoner—p. 2737

Sedimentation Tests in Inflammatory Processes of Small Pelvis—Rollin made comparative studies with macro and micro procedures and also compared the single reading of the reactions with the six-phasic (every fifteen minutes) readings. He reaches the following conclusions: If a good method is employed for instance, that of Kowarski, and if the person performing the test has sufficient practice the micromethod can well serve as a substitute for the macromethod. But because of its greater reliability, the macromethod remains the best for practical application. The micromethod should be resorted to only in cases in which venipuncture is inadvisable. The six phasic sedimentation gives more exact results than

does the simple one, but in gynecology it has no essential advantages over the simple one

Coagulation of Blood During Pregnancy—Farschwich shows that pregnancy influences the coagulability and the viscosity of the blood. There is, however, no definite relationship between blood pressure, coagulation and viscosity, and the state of the one does not permit an estimate of the other. With the progress of pregnancy coagulation becomes accelerated but a strict parallelism cannot be detected. The coagulability is considerably increased at the end of pregnancy. Normal values are reached again on the fifth or sixth day after delivery. The coagulability is practically the same on the day preceding and the day following delivery. The viscosity becomes reduced during normal pregnancy. This decrease is most pronounced during the second half of pregnancy but again reaches normal values on the fifth or sixth day following delivery. The author thinks that influences from the endocrine glands and from the placenta are involved in these changes and that it is desirable to make investigations in this direction.

Enemas of Urine from Pregnant Women in Menstrual Anomalies—After calling attention to reports on the subcutaneous administration of the urine of pregnant women in the treatment of menstrual disturbances, Warschawsky relates his experiences with the rectal application. The urine was that of women whose pregnancy was in the ninth or tenth lunar month. In order to avoid infection (gonorrhea, tuberculosis) and to exclude the action of prolam which may produce serious changes in the ovaries, the urine was boiled and then administered in the form of enemas, which, as a rule, were given twice daily between the seventh and twenty-fifth days of the menstrual cycle, but in some instances also immediately preceding and during the menstrual period. During the first few days enemas of 25 cc were given but later the quantity was increased to 50 cc. In this manner the patient receives daily from 1000 to 2000 mouse units of folliculin. The author points out that this treatment was intended as a substitutional therapy and consequently was employed in cases of secondary hypomenorrhea or oligomenorrhea with manifestations of ovarian dysfunction, particularly in older women. In discussing the action mechanism involved in this rectal therapy, he states that by way of the hemorrhoidal plexus and the hypogastric vein the substance goes directly into the vena cava and thus into the systemic circulation without passing through the liver. He stresses the great resorptive capacity of the rectum. Case reports indicate that the treatment gave results in a number of cases, and, since untoward effects were entirely absent, further trials with this method seem justified.

Clinical Value of McClure Aldrich Reaction in Children N. M. Frishman and S. Ya. Vaysberg —p. 397

The Aschheim-Zondek Reaction—According to Mandelshtam and Kaplun, the Aschheim-Zondek test was accurate in 98.3 per cent of their cases of early pregnancy. The test proved of considerable practical value in cases in which pregnancy was complicated by the coexistence of a myoma or an ovarian cyst. It proved to be of even greater value in the differential diagnosis of extra-uterine pregnancy from inflammatory swellings of the adnexa. A positive test favors definitely an extra-uterine pregnancy, while a negative result does not entirely rule out the existence of an extra-uterine pregnancy with a lowered hormone activity of the trophoblast (dead ovum). Operative intervention is indicated in these cases if the reaction is positive. When negative, the question of intervention must be decided by the clinical picture. The chorio-epithelioma reaction of Aschheim-Zondek proved to be valuable in cases of hydatid mole. It makes it possible to recognize the transition of the mole into a chorio epithelioma as well as to recognize early recurrence of metastases after the operation.

Kelation of Acute Pancreatitis to Operative Interventions on Stomach and Duodenum R. Lauren —p. 323

Rupture of Hydronephrosis H. G. Skarby —p. 361

Endometriosis of Urinary Bladder—Settergren states that endometriosis of the urinary bladder is relatively rare, there being only twenty-two cases on record. His patient, a woman aged 27, complained of painful urination limited to the menstrual period. Cystoscopic examination revealed a tumor, the size of a hazelnut in the vicinity of the right ureteral opening. A second cystoscopic examination performed during menstruation demonstrated an increase in the size of the tumor. The tumor was removed through a high cystostomy operation. The patient was rendered symptom free. Pain on urination limited to the menstrual period, possibly with hematuria, constitutes the one characteristic symptom of endometriosis of the urinary bladder. A cystoscopic examination should be made both in the intermenstrual period and during the menstrual period. The cystoscopic picture may suggest varices, angioma or carcinoma. No treatment is indicated in the absence of symptoms or in patients close to the menopause. Röntgen irradiation of the ovaries is to be recommended in patients of this age requiring treatment because of symptoms. In younger patients presenting symptoms, radical extirpation by laparotomy is the best treatment.

*Significance of Plasma Proteins in Clinic A. H. Johansen —p. 379

Plasma Proteins in Clinic—Johansen says that an understanding of the physiology of the plasma proteins is important in the study of numerous functions in which healthy and pathologic conditions unnoticeably merge into each other. Determination of the total protein and of the most important fractions usually gives reliable information as to the phase of many disease conditions. Determination of the plasma proteins gives more reliable information than the sedimentation reaction concerning the activity of infections, because there is a considerable error in the sedimentation reaction when the disease is complicated with anemia. Attention is called to the significance of the plasma proteins in disorders of the liver and kidneys and to their peculiarities in patients with malignant tumors, especially certain tumors of the bone marrow.

Nomenclature in Danish Pharmacopoei 1933 K. O. Møller —p. 1054

Nephritic Retinitis—The frequency of this disorder does not seem to Ehlers to be decreasing. He says that the reduced number of cases of nephritic retinitis during the years of rationing from 1918 to 1921 might indicate that the disturbance can be influenced by diet. His fifty-six cases afford no evidence of notable improvement in prognosis. There was hypertension in the central artery in all cases, but equally high hypertension in the central artery was found without nephritic retinitis.

MYASTHENIA GRAVIS

FOURTH REPORT THE ONSET AND COURSE OF THE DISEASE

WALTER M. BOOTHBY, M.D.
ROCHESTER, MINN.

Between April, 1932 and May, 1933, we have had at the Mayo Clinic twelve cases of myasthenia gravis. At the recent meeting of the Association of American Physicians I reported¹ in considerable detail the results we had obtained by treatment in these cases with ephedrine and glycine (the amino acid glycine, to be differentiated from the photographic developer glycin). This can be briefly summarized as follows: Ten of the patients definitely improved on treatment with glycine and ephedrine, or the ten who improved all have been able to be up and about and, with the exception of two of the oldest (one woman, aged 79, and one man, aged 69), they have been able to carry on light work, four of the ten showed very marked improvement, one of whom received glycine alone without ephedrine, in two the only result was cessation in the downward progress of the disease (one of these patients recently died from causes not directly attributable to the myasthenic syndrome). In addition to our own cases, I have been indirectly in touch with about as many more, and most of these have also shown improvement. Remen² has reported one very striking example of improvement. In five of six cases in which we have tried to decrease or omit the glycine there was a gradual aggravation of the symptoms, which again improved with administration of sufficient glycine. Therefore, I believe one may feel confident that glycine is of definite benefit in myasthenia gravis.

Lo Harriet Edgeworth³ belongs the credit for the discovery and demonstration on herself of the beneficial action of ephedrine in myasthenia gravis, we have also confirmed her observations. Thomas, Milhorat and Techner⁴ discovered that in a certain type of case classified as progressive muscular dystrophy the patient could be benefited by the use of glycine. Following up

this point I tried the effect of glycine in the treatment of myasthenia gravis, my first report⁵ on the beneficial effect in this disease was made practically simultaneously and entirely independently of a similar report by Remen in Germany.

Myasthenia gravis is by no means as rare a disease as is generally supposed, as is evidenced by the fact that between May 1 and June 10 of this year we have had eight new cases of which only four had been recognized, and the patients came to us as a result of our previous reports¹ on the subject. It is, of course, too early to evaluate the effect of treatment in this recent group. A report, however, of the onset and course of the combined group of twenty cases will, I think, prove timely and will help in the more prompt recognition of the disease. One does not need to emphasize the importance of an early diagnosis in order that the patient may be placed as soon as possible on the appropriate regimen and treatment and instructed how to avoid complications and how to regulate his life so that physical exertion will be decreased to an amount which will not tax the reserves built up by treatment with glycine, or ephedrine, or both.

In table 1 are given the duration of symptoms before diagnosis was made and the total duration of the disease up to June of this year, as well as the order in which the symptoms of the disease developed. Any such tabulation can present only an approximate picture of the course of the disease, which, among the patients who have had a long history, was interspersed with periods of more or less remission and occasional periods of what appeared to be complete intermission.

It will be noted that in seven of the twenty cases (35 per cent) there was a history of an acute infection shortly before the onset of the symptoms characteristic of myasthenia gravis. Thirty-five per cent must certainly be considered a large number to have happened to have an unrelated infection of the upper air passages or other streptococcic infection. On the other hand, it must not be overlooked that the remainder gave no such history, although possibly in the cases of longer duration a mild infection might have been forgotten. Careful study by Dr. Robertson of the muscles obtained at necropsy in two of these twenty cases, as well as the reports in the literature, suggests very strongly that the underlying cause is some type of infecting organism which elects to localize in the muscles in some manner corresponding to localization in joints in chronic arthritis. This suggestion by no means a new one is merely called to attention for the purpose of future observation and study.

The order of the onset of symptoms is with minor variation, consistent and characteristic. First the patient complains of fatigability or of becoming unduly tired and hardly feels able to carry through his ordinary daily routine, as fatigue develops there is frequently blurring of vision due to diplopia which sends the patient to the ophthalmologist or optician for glasses. At this time there may be transient ptosis of one or both eyelids and also, sometimes weakness of the muscles of expression, if the onset of these symptoms has been sudden, the condition has been erroneously diagnosed in some cases as a slight "stroke." Occasionally, after a few weeks, the diplopia and ptosis may clear up and remain absent for months or even years. More frequently weakness of the muscles of the tongue and pharynx develop in a short time or may even precede the diplopia. The first sign of weakness of the muscles of phonation is usually noticed as a phenomenon of fatigue after prolonged talking, such as

character of the disease, even without treatment, and the marked improvement following use of glycine and ephedrine, one should not allow the patient to become discouraged even if the effect of treatment for several months does no more than to stop the progressive course of the disease.

The third group of muscles to become involved is composed of those of the extremities. Sometimes however, the arms or legs may be the first to be noticeably involved. In one of our cases the arms and hands were first involved, and in another the legs, and the muscles of phonation and deglutition were not involved until later. In some the weakness of the arms and legs becomes so great that the patients can walk only very short distances without falling down and then can rise up only after a period of rest. The muscles of the neck are often involved to the extent that the patient has to support his head and, if lying down, to move his head with his hands by grasping his hair. The mus-

17	42	♂	1 month		2 months	1 Fatigability 2 ptosis and diplopia 3 extremities 4 swallowing
18	74	♂	1 month		1 month (died)	1 Diplopia muscles of tongue (chewing) swallowing 2 arms and leg
19	55	♂	3	Influenza Rhino-pharyngitis	2	1 A snap (?) in head 2 nausea 3 talking 4 swallowing general weakness 1 respiratory muscles
20	21	♀	1		2	1 Vocal cord 2 tongue and articulating 3 swallowing 4 arms and legs 1 Nasal twang, 2 speech 3 swallowing 4 extremities

in public speaking or in reading aloud, as fatigue develops, the pronunciation gradually becomes indistinct and slurred and may possess a nasal twang. Weakness of the muscles of deglutition is first noticed as difficulty or fatigue on chewing meat or in swallowing, as a consequence, the patient tends to select a semisoft diet, as the weakness progresses there is regurgitation through the nose, when chewing and swallowing become more difficult the whole picture of the disease rapidly becomes more marked accelerated in part by the weakness secondary to insufficient nourishment, loss of weight may be very rapid. In an actively progressing stage of the disease the patient may be in marked negative nitrogen balance even on a liberal, semisolid diet. At such a time the feeding of a high calory, high vitamin diet in liquid form, through a Rehfuß tube introduced through the nose becomes a necessity, first, to afford sufficient nourishment and secondly to prevent choking and pneumonia from inhalation of food. In an occasional case this method of feeding must be maintained for months and is to be preferred to gastrostomy. On account of the remitting

character of the disease, even without treatment, and the marked improvement following use of glycine and ephedrine, one should not allow the patient to become discouraged even if the effect of treatment for several months does no more than to stop the progressive course of the disease.

The third group of muscles to become involved is composed of those of the extremities. Sometimes however, the arms or legs may be the first to be noticeably involved. In one of our cases the arms and hands were first involved, and in another the legs, and the muscles of phonation and deglutition were not involved until later. In some the weakness of the arms and legs becomes so great that the patients can walk only very short distances without falling down and then can rise up only after a period of rest. The muscles of the neck are often involved to the extent that the patient has to support his head and, if lying down, to move his head with his hands by grasping his hair. The mus-

cular weakness of some patients is so extreme that they may be unable to turn over in bed to raise their arms to their heads or in fact, to make any appreciable movement, and the intercostal muscles even may become involved. There is both pathologic and clinical evidence that occasionally the heart muscle is affected by the disease. In one case dyspnea was produced by the extreme weakness of the pharyngeal and laryngeal muscles, which permitted the epiglottis to fall backward and to obstruct the passage of air into the lungs like a flap valve. This necessitated, first, tracheotomy and then artificial respiration for ten days in the Drinker respirator, which was followed by improvement to the extent that the patient was up and about his room. He later died from causes not directly attributable to the myasthenic syndrome.

Exercise or use of the muscles involved always produces rapidly increasing fatigue. For example, a patient may be able to walk half a block without much difficulty and then rapidly becomes weak and may fall. The patients are almost invariably better after a short rest and especially in the morning. However an occa-

sional patient will have considerable difficulty in dressing in the morning and then be in fairly good condition during the forenoon, with a marked period of depression around 4 or 5 p m. The so-called myasthenic response of the muscle to electrical stimulation is by no means an invariable phenomenon.

As pointed out in the foregoing and in the table the course of the disease is usually gradual, with involvement of first one group of muscles and then of another, with irregular periods of remission or intermission. On the other hand, some patients present a very fulminating type of the disease, with rapid and progressive involvement of various groups of muscles, which may end in death within four or five weeks after onset of the disease, from profound weakness, inanition and dehydration, unless proper steps are taken in time to prevent the latter complications.

On all of our patients we have carried out extensive investigation of the chemistry of the urine and blood. The details of these studies will be reported elsewhere, as they are of more interest to the student of intermediary metabolism than to the clinician. The practical results, however, may be briefly summarized as follows:

1 The blood shows no characteristic or consistent change, in either the nitrogenous or the inorganic constituents, which is of value in the diagnosis of the disease.

TABLE 2—Amount of Creatine Nitrogen in the Urine

Case*	Males†		Case	Females†	
	Amount of Creatine Nitrogen Daily			Amount of Creatine Nitrogen Daily	
	Before Taking Glycine, Mg	Maximum While Taking Glycine, Mg		Before Taking Glycine, Mg	Maximum While Taking Glycine, Mg
1	30	110	2	0	110
2	40	120	3	70	80
6	10	150	4	10	60
7	30	90	9	170	200
8	40	100	14	20	170
10	20	40			
12	40	430			
13	20	190			
15	20	110			
16	10	60			
17	20	40			
19	20	40			

* Numbers correspond with those of table 1.
† Quantities of 20 mg of creatine nitrogen or less are open to question but as these values were obtained for several days they probably indicate that at least traces were present.

2 The urine shows no abnormal constituent other than creatine. In table 2 are listed the average amounts of creatine nitrogen excreted daily, before administration of glycine was started, a few of the patients had been receiving ephedrine for a varying length of time when the urine was first examined by us. The maximal amount of creatine nitrogen excreted after the patient had been receiving glycine for from two to six weeks or more is also given. As can be seen administration of glycine causes a definite and sometimes a very marked increase in the creatine nitrogen. Later, a decrease in the amount excreted sometimes occurs, which may or may not be coincident with clinical improvement. The reaction is quite similar in both men and women. This increase in excretion of creatine following administration of glycine is not confined to patients with myasthenia gravis, for we obtained it in three normal women who were used as controls and also in a few other individuals who did not have myasthenia gravis.

SUMMARY

The diagnosis of myasthenia gravis in the fully developed case is easy and is based on the history and the progressive development of the characteristic type of weakness outlined. True muscular paralysis from other causes, however, must be ruled out by detailed neurologic examination. Probably the greatest difficulty arises in the slowly developing case, in knowing just when in the progress of the disease, one is justified in making a positive diagnosis of early myasthenia gravis as opposed to some neurotic or functional disturbance. Unfortunately, laboratory data are of little practical help in arriving at the correct diagnosis, although the course of excretion of creatine is of considerable value in following the progress of treatment. Both ephedrine and glycine are valuable drugs in the treatment of the disease, and by their proper use a large proportion of patients with myasthenia gravis is benefited, many are so greatly helped that they can continue to work.

THE EFFECTS OF GLYCINE (GLYCOLL) IN MUSCULAR DYSTROPHY

WITH ESPECIAL REFERENCE TO CHANGES IN STRUCTURE AND COMPOSITION OF VOLUNTARY MUSCLE

The report of the remarkable therapeutic action of glycine¹ in progressive muscular dystrophy by Thomas, Milhorat and Techner² has been followed by widespread trial of this substance in the dystrophies and in other diseases primarily involving the muscles. Beneficial effects in muscular dystrophy have been substantiated by Kostakow and Slauck,³ Chanutin, Butt and Royster,⁴ and Beard and Tripoli.⁵ Boothby⁶ and Remen⁷ have shown that glycine is of value also in the treatment of myasthenia gravis. It would appear, however, that the treatment of muscular dystrophy has not been successful in many instances and that certain patients suffering from this disease do not respond to glycine therapy. This is evident from the reports of Boothby,⁶ Milhorat,⁸ and Brand and Harris.⁹ Aside

Rowntree has brought to our attention three additional cases of progressive muscular dystrophy in which glycine failed to bring about improvement as well as one case of myasthenia gravis that responded favorably to the administration of glycine.

from the suggestion of the latter that glycine may be effective only in certain forms of muscular dystrophy, there is at present no explanation for the apparent failure in these instances. Conclusions in regard to the efficacy of the treatment have been based largely on the clinical observation of the changes in the physical function of the muscles. As slight changes in muscle function are not easily detected, it is to be expected that differences of opinion would arise in regard to the effects of the therapy.

To avoid this difficulty we have utilized in the present study in addition to the usual physical procedures for estimating therapeutic action, the more objective method of chemical and microscopic examination of the muscle. A great incentive to the use of this method of approach was the opportunity it offered for learning how the glycine acted on the muscle. In the evaluation of results of the treatment, information obtained from the biopsies of the muscles has been considered in connection with the clinical response and also in relation to the excretion of creatine and creatinine in the urine.

The results obtained by the use of glycine therapy in eight cases of progressive muscular dystrophy and in one case of generalized chronic myositis are reported.¹⁰ Of the dystrophies, six conformed in all respects to the characteristic clinical picture (five showed a familial history of the disease), while in two others the diagnosis was not as clearly established. The muscles of the latter showed essentially the same histologic picture as the true dystrophies (cases 2 and 3). The group included both early and advanced stages of the disease.

The diagnosis of chronic myositis was made in patient 9, a woman, aged 65, whose case from the clinical standpoint could be readily included as one of muscular dystrophy and was at first so considered. However, biopsy of the muscles indicated the existence of a marked chronic inflammation with cellular exudate and fibrous tissue proliferation while the muscle fibers were comparatively normal. The usual symptoms of muscle inflammation were lacking.

Besides glycine, certain auxiliary and supplementary measures have been utilized in the treatment of these conditions. High protein diets, gelatin, beef extract and ephedrine have been tested, and a consideration of the effects of these substances is included.

EXPERIMENTAL

The general procedure employed in the study of this group of patients is outlined in the protocols. The excretion of creatine and creatinine was measured before and at frequent intervals after treatment, during periods when the patients received house diets from which meat and meat soups had been omitted. The method of Folin¹¹ was used.

Specimens of muscle were taken from the vastus externus.¹² This muscle seemed to be fairly representative of the condition of the larger voluntary muscles, although others were often more severely affected. Post-treatment biopsies were taken from the same portion of the muscle as the first specimens. In two instances, however, the corresponding muscle of the opposite leg was utilized for the second biopsies, and third biopsies were performed later, close to the original incision, to verify the results. Nitrous oxide anesthesia

was used except in a few cases in which procaine hydrochloride was substituted. Precautions were taken to prevent the anesthetic solution from entering the muscle proper. The fascia lata was exposed and divided without stimulation of the muscle. A specimen was then removed as rapidly as possible and divided into two portions of about 0.5 Gm each. One of these was weighed quickly and immediately ground with sand in a chilled mortar containing cold 5 per cent trichloroacetic acid. The filtrate obtained was used for analysis of the muscle extractives.

The remainder of this portion of the muscle was utilized for the determination of water, ether extract (extraction of the dried specimen in a Soxhlet extractor for seventy-two hours), and total nitrogen (by the macro Kjeldahl test on the fat free residue). A second separate specimen was taken from the exposed muscle for the histologic studies. The possibility of misinterpretation due to lack of uniformity in the diseased muscle was thus lessened to some extent. Chemical and histologic analyses have agreed in eighteen of the twenty biopsies in which both were done.

RESULTS

Although glycine therapy, so far as clinical improvement is concerned has proved to be of rather limited value in the patients with the muscular dystrophy syndrome, there is, nevertheless, evidence for believing that the treatment has had beneficial effects. These are more noticeable in the children than in the adults. One of the children (patient 4) after three months of treatment with glycine regained the ability to stand for brief intervals when support was afforded. In another child (patient 6), after a similar period contractures of the hamstring muscles were ameliorated. Patient 5 showed little change, although the disease apparently has made no further progress. It is uncertain whether improvement has occurred in two children who showed early symptoms of muscular dystrophy. While the latter have been treated only fifteen weeks, Milhorat's patients responded favorably in less than this time. Evidence of improved muscular function is even less tangible in the adult patients and no specific instance can be cited in which there has been undoubted gain in the ability to perform muscular movements that can be ascribed to administration of glycine. Two of the adult patients (patients 1 and 2), however, assert that they have gained strength and that fatigue occurs less readily than before treatment. They testify also that certain operations, such as dressing and various minor movements are accomplished with less effort and that an erect sitting position now can be maintained for longer periods than previously. It will be seen that the assertions of these patients are supported to some extent by data provided by the muscle biopsies. A third adult (patient 3) has failed to maintain the improvement that appeared during the early period of treatment.

While the gains in muscle function did not fulfill expectations, it should be mentioned that administration of glycine has been of considerable benefit in other ways. Among all the patients but in the children particularly, the mental and physical activity has been stimulated as a result of the treatment. No ill effects have been noted as a consequence of glycine therapy. Kidney function as measured by urea clearance determinations has remained unchanged following long periods of glycine administration.

Glycine proved to be of decided value in the case of generalized chronic myositis that was discovered in

¹⁰ We are indebted to the staffs of the Departments of Neurology and of Pediatrics for permission to study these patients and for assistance.

¹² The authors are indebted to Dr Philip Ehrig for performing the biopsies.

connection with the studies on muscular dystrophy. In this instance several weeks of glycine feeding enabled the patient to rise to a sitting position without help whereas powerful assistance had previously been required. The ability to walk improved appreciably.

All the patients exhibited creatinuria to a pronounced degree which was further augmented with only two exceptions, by the administration of glycine. In a few instances the creatinine excretion also increased. Both the creatine and the creatinine output remained comparatively stable over long periods with a constant level of glycine feeding. The gradual inversion of the creatine-creatinine ratio reported by Milhorat⁸ and by Kostakow and Slauck³ has not been observed in two cases in which creatine excretion was studied under controlled conditions for long periods. In chronic myositis, glycine therapy caused the excretion of creatine to increase considerably, while a similar observation has been made in an emaciated cachectic female who showed extreme wasting of the muscles, caused apparently by starvation. It appears, therefore that increased excretion of creatine in the urine after glycine occurs not only in progressive muscular dystrophy but in a variety of other conditions in which the muscles may be involved.

Twenty-one biopsies of muscles have been made in thirteen cases, although the results for only nine of the latter are discussed here. The extensive degeneration of the voluntary muscles in progressive muscular dystrophy has been described by Erb,¹³ Lorenz,¹⁴ and others, and our observations are in accord with those reported by these workers. A loss of substance and of structure with replacement by fat and fibro-areolar tissue was to be seen in varying degrees in all cases, dependent roughly on the duration of the disease. Both hypertrophied and atrophied fibers commonly were present in the same muscle. Distortion, fraying, vacuolization, and fission of fibers constituted other changes of importance. The internal structure of the fibers at times was obliterated, and in its place could be seen only homogeneous, unevenly stained material. The quantity of myohemoglobin present in the remaining fibers appeared to be reduced, although individual variation in this respect was considerable. Visible nuclei were increased in number, while the distribution in the fibers was abnormal.

Analyses of the specimens of muscle revealed that characteristic muscle constituents were greatly reduced in concentration, in some instances to small fractions of normal values. In advanced cases the muscles contained only from 5 to 10 per cent of the normal concentrations. Earlier cases, with but partial functional incapacity, contained as much as 50 per cent of normal. Most conspicuous was the deficiency of creatine, which appeared to be diminished to a greater extent than the other substance that have been determined. Exceptions were encountered in the two cases of longest duration, in which the loss of creatine from the muscle had been in approximately the same proportion as the loss of other water soluble extractives. In all the patients, the widespread infiltration of fat and the substitution of connective tissue (estimated by staining reactions) for muscle fibers explained in large part the greatly reduced concentrations of the substances concerned with the normal activity of the muscle. These factors alone, however, were not sufficient to account for the low

values observed, and it is probable that a marked deficiency of water soluble extractives and other characteristic muscle components existed in the surviving muscle fibers. A relatively high total nitrogen in several of the more badly degenerated muscles could be traced to the substitution of fibro-areolar tissue.

Muscle biopsies have been performed after periods of treatment with glycine in six cases, and chemical and histologic data are available for comparison with similar data from pretreatment specimens. Of the eight post-treatment specimens that were subjected to histologic examination, six were of a better quality than the preceding specimens, one was of a poorer quality, and one showed no appreciable changes. An identical distribution was encountered in the results of the chemical analyses. A case in which retrograde changes were suggested by chemical analysis has been classified as showing no gain or possibly slight gain histologically. Actually, in this instance in the later specimen, lowered concentrations of certain extractives were counterbalanced by a higher fat content, hence there was probably no actual change of fiber quality. In the remaining case in which the results of the biopsies were doubtful, the microscopic examination indicated a slight progression of the degeneration, while the chemical changes on the contrary pointed toward a moderate degree of recovery. Possibly the discrepancy may be explained by the short period of treatment in this instance (eleven weeks), since it is not improbable that chemical changes would precede morphologic alterations. One may summarize the evidence provided by the biopsies by stating that in four cases improvement was indicated, while in two others, because of the conflicting data or lack of significant differences, there was no definitely established trend. Additional post-treatment biopsies in two cases, seven months after the last preceding biopsies yielded results substantiating those obtained previously from the same case.

Histologically, the post-treatment specimens differed from those taken before glycine was administered by the greater uniformity in fiber size, better staining reactions and decreased numbers of visible nuclei. Cross striations and longitudinal fibrils were to be seen more clearly. The fat content of the muscle was greatly decreased in most cases, and more myohemoglobin appeared to be present. Photomicrographs showing representative muscle fibers of one of the patients before (fig 1) and after (fig 2) treatment illustrate certain of the changes that have been described.

The muscle specimens taken after treatment showed quantitative differences in chemical composition, which likewise suggested regeneration. The restoration of the muscle appeared to be of a general nature, involving all the muscle constituents that have been studied. Total nitrogen was increased, particularly in the more advanced cases. Creatine concentrations were from two to four times the original figures, and the total acid soluble phosphorus showed like differences. Since the gains in creatine concentration did not exceed the similar gains in other water soluble extractives, the relative deficiency of this substance in the muscle remained uncorrected. Diminution of the proportion of fat in the muscle following the treatment was insufficient to account for the increased concentrations of extractives that have been noted. However, the composition of the muscles of the muscular dystrophy cases was still far from normal after varying periods of treatment, despite the gains that apparently had occurred. Owing to the lack of space for adequate dis-

¹⁴ Lorenz H A. *Die Muskelerkrankungen in Spezielle pathologie und Therapie* (Nothnagel) 11: part 3 1904.

cussion, the chemical data from these and other cases will be presented elsewhere in detail.

The absence of unmistakable evidence of improvement in the function of the muscles of these patients led to the trial of several supplementary measures. These included high protein diets, gelatin, beef extract and, in one case, ephedrine. Details are described in the protocols. It is believed that the high protein diets (2 Gm per kilogram for adults, from 3 to 4 Gm per kilogram for children principally in the form of meat) were of definite benefit. Somewhat greater progress (as suggested by muscle biopsy) was made in case 1 during the second treatment period coincident with the use of such a diet. High protein diets, beef extract and gelatin, singly or in combination appeared to be ineffective in the quantities given when glycine was omitted.

As a consequence of the successful use of ephedrine in myasthenia gravis by Edgeworth¹ this drug has been tested in conjunction with glycine in case 3 which

Fig. 1 (case 4)—Control muscle biopsy, Jan. 10, 1933 illustrating a giant fiber that presents almost complete loss of internal structure, vague suggestion of cross striation remaining rather an extreme example. Opposed to this are minute fibers embedded in a fibrous matrix with occasional normal fibers interspersed. Slightly reduced from a photo micrograph with a magnification of 1,021 diameters.

failed to respond clinically when the latter was given alone. While the general condition of the patient was improved, there has been no convincing gain in muscular function. Administration of ephedrine doubled the excretion of creatine which had already been augmented considerably by the feeding of glycine. Muscle sensations of the nature of those described by Thomas, Milhorat and Techner² were pronounced in this patient and were concurrent with periods of excessive creatine excretion after glycine and again after ephedrine.

COMMENT

The biopsies as a whole provide considerable evidence for regeneration of muscle and practically none that indicates further deterioration. Although based on a small number of observations, the distribution of the results favors the view that improvement in the volun-

tary muscles actually had occurred. The use of muscle biopsies for evaluating results of treatment may be subject to errors arising from a lack of uniformity in the muscle, and undoubtedly this factor is responsible for certain discrepancies that have been observed. However, information obtained by performing additional biopsies after further periods of treatment confirmed earlier observations. Clinically, the improvement in the patients suffering from progressive muscular dystrophy has not progressed to the extent that might be expected on the basis of the indicated change in the composition of the muscle. Yet, in view of the extensive deterioration of the voluntary muscles (all of the post treatment biopsies were done in advanced cases) and the fact that marked abnormality persisted even after extended periods of treatment, a rapid clinical response to glycine therapy was not to be expected. It is believed that the evidence of improvement obtained by direct examination of the muscle is, therefore, a more sensitive guide to the earlier effects of glycine therapy than are measurements of muscle function or creatine excretion.

The results are sufficiently indicative of improvement to suggest continuation of glycine therapy. It is hoped that the present studies may be extended over a sufficient period of time to permit a statement of definite conclusions in regard to the effects of prolonged administration of glycine and of the supplementary substances that have been employed. Occupational therapy has been utilized during recent months as an adjunct to the dietary treatment.³ The use of this or of some other form of systematic controlled exercise is strongly advocated.

SUMMARY

The effects of glycine feeding have been studied in nine cases of progressive muscular dystrophy for periods up to fourteen months. Little tangible evidence of improvement in muscular function has been obtained.

Muscle specimens removed at biopsy after treatment were distinctly better in quality, chemically and histologically, than similar specimens taken before treatment. Restoration of various characteristic muscle components accompanied regeneration of the muscle fibers.

High protein diets, beef extract and gelatin proved to be helpful supplements to glycine. Ephedrine has been of value in one case.

A patient with generalized chronic myositis that closely simulated the clinical picture of muscular dystrophy showed considerably improved muscular function following glycine therapy.

Despite the marked improvement in the structure and composition of the muscles in progressive muscular dystrophy after treatment with glycine (as indicated by examination of the biopsy specimens), a great disparity with the normal remained, probably sufficient in many cases to account for the failure of muscular function to be restored to a greater extent. The possibility of inducing further regeneration, perhaps sufficient to bring about unquestioned clinical improvement, remains to be tested.

PROTOCOLS

CASE 1—H. M., a white man, aged 28, had had a progressive muscular dystrophy with pseudohypertrophy for nineteen years. The patient was exceptionally obese, weighing 90 Kg., he presented a typical example of the more advanced stages of the disease with complete loss of the use of the legs and almost total inability to perform movements with the arms. The muscles of the back were extensively involved. The calves

¹⁶ Occupational therapy has been carried out under the direction of Miss Helen S. Willard of the Philadelphia School of Occupational Therapy.

and thighs showed pronounced pseudohypertrophy. The shoulders and arms exhibited atrophy with a commensurate loss of power. The movements were restricted to those required for eating and personal care. The family history was negative.

The patient excreted in the urine in an average twenty-four hour period 0.173 Gm of creatinine and 0.694 Gm of creatine (as creatinine). Seventy-seven per cent of 2 Gm of creatine given by mouth reappeared in the urine within forty-eight hours.

A specimen of the vastus externus muscle showed degenerative changes of extreme nature. There was extensive replacement of muscle by fat. Few of the muscle fibers were normal. Acid soluble extractives were present in low concentration.

Treatment was divided into two periods of approximately five months and seven months respectively. After the preliminary biopsy and the study of the creatine and creatinine excretion in the urine the patient was fed 15 Gm of glycine daily for seven weeks, then 23 Gm daily for five weeks, and again 15 Gm daily for ten weeks. An ordinary house diet accompanied the treatment during this period. After five months of glycine feeding, a second biopsy was performed. Subsequently, the feeding of glycine was resumed at the rate of 15 Gm daily in conjunction with a diet high in protein, particularly meats. The diet also included 15 Gm of gelatin and, during the last two months, 5 Gm of beef extract daily. A third biopsy was then done.

A few weeks after first receiving glycine the patient stated that he could rise from a lying position and perform certain other movements with greater facility than he could before. At the present time the patient believes that he fatigues less easily. It is difficult for an observer to see any improvement, however, and his condition is practically the same, except for a moderate loss of weight, as it was previous to treatment a year before. Nevertheless, there is no evidence of the progression of the disease, as there had been during previous years.

During the first five weeks of glycine administration the average excretion of creatinine was 0.300 Gm, creatine (as creatinine) 1.090 Gm. Extra creatine (from glycine feeding) subsequently showed no appreciable decrease. Following fifty weeks of treatment when glycine had been discontinued the patient excreted 0.244 Gm of creatinine and 0.682 Gm of creatine (as creatinine) daily during an eleven day period.

Certain features in the appearance of the muscle under the microscope at the end of the first period suggested that some regeneration had occurred. The muscle fibers appeared to be more nearly normal. Cross striations were clearer, and there was less fraying and separation of the longitudinal fibrils. The fibers contained more myohemoglobin. The close of the second period of treatment showed further and more definite indications of an improvement in structure. While variation in fiber size persisted, it was somewhat less marked, and the muscle bulk appeared to be increased. The fiber quality was markedly bettered.

Total nitrogen, creatine and total acid soluble phosphorus were present in higher concentrations in the specimens removed at the end of the first period. Ether extract was much lower in this specimen than in the original. The third biopsy done six months later, substantiated previous gains and showed furthermore that they had been extended. Analyses at this time yielded values that were from three to four times as great as those observed before treatment in a specimen from an adjacent portion of the same muscle.

CASE 2—L. G., a Negro man, aged 45, weighing 50 Kg, complained of muscular dystrophy which had had a gradual onset between the ages of 28 and 30. During the following ten years there had been little change in the patient's condition. Subsequently slow progression of the disease during the five years preceding the present treatment had resulted in the gradual loss of the use of the legs and to a considerable extent, of the arms. The muscles of the shoulder girdles were most severely affected. The hands were not involved. The patient complained of pains in the joints, but these were thought to be of postural origin. Although certain aspects of this case were not fully in accord with the diagnosis histologic examination of the muscle revealed degenerative changes similar to those observed in the true muscular dystrophies. There had been no similar cases in the family. The patient excreted on the average

during twenty-six days preceding treatment 0.460 Gm of creatinine and 0.206 Gm of creatine (as creatinine).

Treatment in this case also was divided into two periods. During the first, glycine was given at the rate of 15 Gm daily with 10 Gm of gelatin. No glycine, as such, was administered during the second period, however, the diet contained gelatin and an abundant allowance of meat, 5 Gm of beef extract was given daily.

Toward the end of the first period and particularly at the beginning of the second, the patient appeared to be able to move his legs with greater facility and seemed improved in other ways as well. The gains made were not sustained, and little if any progress has been made subsequently. At present the condition appears to be stationary so far as clinical evidence is concerned, although the patient believes that he has been benefited.

After glycine was started at the beginning of the first period, the excretion of creatinine remained unchanged at 0.444 Gm. every twenty-four hours, while creatine (as creatinine) rose to 0.356 Gm. In this case, also, there was no reduction in the output of extra creatine. In comparison with the excretion before treatment, creatinine excretion after eleven months had

Fig. 2 (case 4)—Muscle biopsy after glycine therapy, April 18, 1933. The fiber presenting normal morphology and diameter. Striation is somewhat clearer in this instance than in the majority of fibers although all show distinct structural improvement and greater uniformity of size. Slightly reduced from a photomicrograph with a magnification of 1,021 diameters.

decreased to 0.370 Gm, and creatine (as creatinine) had increased from the original value to 0.318 Gm.

The muscle biopsy at the close of the first treatment period revealed somewhat greater uniformity among the fibers. Unusually large fibers persisted, but the extremely small degenerated fibers were no longer to be seen. The muscle bulk remained unchanged. At the conclusion of the second treatment period, although the quality of the muscle seemed improved in comparison with the preceding specimens, the impression created was still one of marked abnormality.

The chemical analyses failed to provide any conclusive evidence in this case of restoration of muscle. At the end of the first period the only significant change was the higher total nitrogen concentration (possibly due to a higher proportion of connective tissue). A lowered concentration of creatine in the specimen obtained at the close of the second period was accounted for by the greater fat content. The acid soluble phosphorus in this instance was considerably increased, particularly when the change in fat is considered. Prolonged administration of a high phosphorus diet (beef extract) may have had a bearing on this change.

CASE 3—Rose M., a white woman, aged 27, weighing 67 Kg, had symptoms on which the diagnosis of progressive muscular

dystrophy could not be established with certainty. There had been no other cases in the family. The onset dated back to two pregnancies in close succession. During the subsequent seven years progressive wasting of the muscles of the shoulder girdles of the lower extremities and of the proximal portion of the upper extremities had occurred. Creatinuria was marked. After 15 Gm of glycine daily (plus 2 Gm of protein per kilogram for seven months) there is little reason for believing that the patient has been helped so far as muscular function is concerned although early in the treatment favorable response apparently had been obtained. The administration of ephedrine (three eighths grain [0.024 gm] daily by mouth) likewise had no lasting effect on muscular function but was helpful because of its action in restoring peripheral circulation.

The specimen of muscle obtained before treatment exhibited mild degenerative changes in the fibers. Striation was indistinct and separation of the longitudinal fibrils gave to the muscle fibers a frayed appearance. Staining characteristics were slightly subnormal. There was considerable fat present. A specimen of muscle obtained after treatment showed mild improvement histologically. Chemically the noteworthy change was a significant increase in the phosphocreatine concentration. Other extractives did not change proportionately. The fat content was lowered.

CASE 4—A S, an Italian boy, aged 8 years, weighing 23 kg, had vomiting muscular dystrophy dating from a severe attack of vomiting at the age of 3. Involvement of the muscles appeared shortly afterward and had progressed from that time. The disease had previously developed in an elder brother. At the time that treatment was begun the patient was unable to stand and could rise to a sitting position only by considerable exertion. The upper extremities were not as severely affected. Involvement was uniformly bilateral. The calves showed pseudohypertrophy. In an average twenty-four hour period before treatment there was excreted in the urine 0.204 Gm of creatinine and 0.258 Gm of creatine (as creatinine).

A specimen of muscle taken before treatment showed that degeneration was far advanced, with extensive replacement by fat and fibrovascular tissue. Few of the muscle fibers that remained were normal in any way, many presenting a glassy homogeneous appearance (fig. 1). Results of the chemical analysis were in accord with the histologic observations. The concentration of the acid soluble extractives was very low. Total nitrogen was reduced far less than other constituents, no doubt because of extensive replacement of muscle by fibrous tissue.

After 10 Gm of glycine daily for twelve weeks in conjunction with a high protein diet after the first three weeks, a second muscle biopsy was performed. Subsequently, glycine therapy was resumed.

The patient previously dull and sluggish became much more active and energetic after a few weeks of treatment. While before he had lagged behind the other children of the group, he soon equaled or surpassed those in whom the disease had progressed to about the same extent. At the end of three months of treatment the patient attained the ability to support himself in a standing position when held erect. However, little further progress has been made.

The average daily excretion of creatinine for twenty-four days after glycine therapy was started was 0.212 Gm and of creatine (as creatinine) 0.375 Gm. Following the conclusion of twelve weeks of therapy the excretion in the absence of medication was 0.147 Gm of creatinine and 0.249 Gm of creatine (as creatinine).

The post-treatment specimen of muscle showed considerably less degeneration than did that taken before treatment. The muscle bulk was increased. The fibers were far more uniform and did not present the glassy appearance that had characterized the earlier sample. Cross striation remained indistinct in the main, although certain fibers showed practically normal structure (fig. 2).

Creatine and total acid soluble phosphorus were higher than before in proportion roughly to the improvement indicated by the histologic studies. Because of the extent of the disability of the patient and the pronounced degeneration observed in the muscle before treatment the fact that a response was obtained was especially encouraging.

CASE 5—J M, a white boy, aged 11 years, weighing 28 kg, had progressive muscular dystrophy with pseudohypertrophy. He had been unable to stand for about two years. There were marked contractures of the hamstring muscles. Treatment was the same as in case 4. There has been little clinical improvement.

The muscle before treatment showed extensive fibrous replacement. Badly degenerated fibers predominated. There was great variation in size with many excessively large fibers. In the specimen taken after treatment the fibers were more uniform and a degree of improvement in the quality of the muscle was observed. Chemical analysis also suggested a moderate gain.

CASE 6—H M, a boy, aged 10 years, weighing 27 kg, a brother of patient 5, had progressive muscular dystrophy with similar manifestations to those in case 5 although not as far advanced. Treatment was given as reported in case 4. Minor indications of partial restoration of muscle function were observed while the contractures of the thigh muscle were partially relieved.

The muscle before treatment showed the usual marked variation in the size of fibers. Certain of the fibers were homogeneous and glassy without detectable cross striation. There was moderate fibrosis and fat infiltration. The microscopic appearance after treatment showed no improvement with possibly some added evidence of degeneration as compared with the pretreatment specimen. In contrast to these observations the chemical studies indicated that the muscle had improved.

CASES 7 and 8—Negro boys, aged 12 and 13 years, brothers, showed early progressive muscular dystrophy. Weakness of the muscles of the shoulders, arms, back and legs, first noticed about nine months before, had become progressively worse. The loose shoulders, lordosis and swaying gait were well defined. The calves were hypertrophied. The muscles showed the characteristic alterations that have been described, although in less marked degree. Ten grams of glycine daily with a house diet failed to bring about any appreciable change in the condition of the patients over a period of three months.

CASE 9—H T, a woman, aged 65, had generalized chronic myositis. The onset three years before had been insidious, with progressively increasing muscular weakness. Pain and paresis were absent. The patient lacked sufficient strength to support herself and could not rise to a sitting position without considerable assistance. There was proximal wasting of both the upper and the lower limbs. The facial muscles were also involved. Reflexes were diminished. The patient's temperature was 100 F on admission. It subsided subsequently but tended to undulate. Eosinophilia was absent.

Aside from the advanced age at the onset, the syndrome closely resembled that of progressive muscular dystrophy and it was only with the aid of the information obtained from the muscle biopsy that the differentiation was made. Marked chronic inflammation existed in the muscle. Some fibrous tissue reaction had occurred, and there was considerable cellular exudate that at many points spread the muscle fibers apart. The fibers were relatively normal in size and staining reactions, although cross striation in many was indistinct. On the whole, fiber quality was fair.

Compared with muscular dystrophies of the same duration the chemical changes in the muscle in this instance were relatively moderate. The acid soluble phosphorus was lowered to about half of the normal. Creatine was reduced far more proportionately, than the phosphorus.

Before treatment, the patient excreted in an average twenty-four hour period 0.304 Gm of creatinine and 0.253 Gm of creatine (as creatinine). The administration of glycine for sixteen days caused the creatinine excretion to increase to 0.365 Gm, while creatine increased to 0.340 Gm.

The feeding of glycine at the rate of 15 Gm daily was accompanied by an unmistakable return of strength to all groups of affected muscles. The patient could again walk short distances without aid or support. The greatest response was observed in the muscles of the back, and the ability to rise unassisted to a sitting position was recovered. The general condition was greatly improved. After six weeks of glycine administration the treatment was interrupted by a severe bronchitis. Bronchopneumonia developed and terminated fatally.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. BOOTHBY AND DR. RICHOLD, CLARK,
KINCHEY, CUSTER AND MCCONNELL

HARriet EDGEWORTH PH.D., Tucson, Ariz. Judging from the 100 cases from which I have heard my own experience has been typical. None were correctly diagnosed in an early stage of the trouble. The only symptom is a fatigue which is hard to appraise, as there is no reliable test for it. It may be limited to a few muscles, e.g., eye, jaw or heart and also at first it may be transitory and disappear on rest. That is, the patient may complain of it only after unusual exertion or during a cold or a menstrual period. When I tried under controlled conditions the whole gamut of drugs, endocrine preparations and physical therapy, no benefit resulted. Exposure to strong sunlight, heat, cold, menstruation, worry, excitement, respiratory infections, depressant drugs and over-exertion all affect the symptoms adversely. Because of similarity in the muscular weakness to that occurring in Addison's disease, a suprarenal deficiency has been suspected. Ephedrine differs from epinephrine by only three atoms in a complex molecule. Reports indicate that glycine may be a stimulant of the suprarenal medulla. Marked vasomotor symptoms were prominent in my own case after I became helpless but subsided on the use of ephedrine. On the other hand the ingestion of fresh cortex and the use of all the available suprarenal extracts have not produced any marked improvement in the symptoms of myasthenia gravis. After the best clinical help available and all the reported remedies failed to arrest the progress of the disease, it was felt that a careful chemical study might reveal small changes in such important constituents as sulphur, nitrogen or phosphorus that might be significant. But the only positive observation in all this painstaking and laborious work was a lowered excretion of creatinine and a creatinuria of about 150 mg. daily. This was surprising in a patient who was totally helpless. Swallowing, speaking and breathing were difficult and there was a chronic cyanosis with alarming cyanotic attacks at times. A creatinuria had been reported before in this trouble as well as in other disorders in which asthenia is a prominent symptom, but its relation to an abnormal muscle metabolism or a means of its control was unknown. In fact, in 1920 I found only one chemist who considered it of significance. But a new point of view has developed in muscle chemistry. Unforeseen constituents (such as phosphocreatine, adenine nucleotide and adenosine) in new roles of metabolic interest have been discovered. The energy of contraction is now believed to be supplied by the decomposition of phosphocreatine. Hence the loss of creatine may be as disabling to patients with muscular disease as sugar is to the patient with diabetes. How ephedrine produces a continuous improvement in some patients with myasthenia gravis is unknown. The daily ingestion of it over a period of three years has changed me from a totally helpless bedridden person to my present condition, wherein I live a comparatively comfortable and pleasant life of some usefulness. I have taken glycine daily for several months, discontinued it for a month and then resumed it without demonstrable beneficial effects, but the apparently beneficial effects on other patients using glycine has thoroughly aroused my interest.

DR. FREDERICK P. MOERSCH, Rochester, Minn. Thanks to the observations of Dr. Edgeworth the medical profession has taken a new lease on life regarding muscular diseases. Since her contribution three years ago, many laboratories and hospitals have been working on this problem of muscle disease. My associates and I have had five cases of progressive muscular dystrophy in which glycine was used. One of these patients seemingly is somewhat better. The other four are no worse and no better. The glycine treatment in dystrophies has not been extremely encouraging. We do not do biopsies as a routine in our dystrophies. These patients have long remissions and it seems conceivable that a patient might have an attack and have a spontaneous recovery. Dr. Edgeworth noted the beneficial effects of ephedrine three years ago, and since that time we have used it as a routine until recently. We now start the patients on glycine. Thus far we have had twenty patients with myasthenia gravis on glycine twelve of whom have been under treatment for a considerable period. Ten are

improved, five distinctly improved, one is stationary and one patient died of unrelated causes. The nature of myasthenia gravis is unknown. There are a tremendous number of theories and yet none of them seem to hold up under clinical scrutiny. It seems that infection plays a part. [Two slides from cases of myasthenia gravis were demonstrated, showing marked round cell infiltration, increase of nuclei and changes in muscle fibers.] These observations suggest that one may be dealing here with some infectious process and it may be that myasthenia gravis is related in some roundabout way to dermatomyositis, scleroderma or even muscular dystrophy.

DR. ERWIN BRAND, New York. From the analysis of the papers by Thomas and by Milhorat I am under the impression that out of their eleven cases of muscular dystrophy only case 1 and, perhaps, case 3 showed definite improvement on the administration of glycine. Since these two cases showed an almost negligible creatinuria in spite of their extensive incapacity it is questionable whether they were cases of progressive muscular dystrophy similar to those that have been studied. One should consider the possibility that their two cases were related to myasthenia gravis. My experience with glycine therapy in muscular dystrophy coincides with that of Dr. Moersch. Although in some of the children under my care the mothers were of the opinion that there was some slight improvement in the ability to walk and in general activity I was not aware of any striking beneficial results on examination. I kept some of my patients on meat-free diets for a long time for special studies. Others have received their ordinary regular diet plus glycine. I had a number of patients on a very high protein intake plus glycine. One patient received a diet containing 100 Gm. of protein plus 25 Gm. of glycine plus from 50 to 100 Gm. of casein daily for two months, the patient excreting about 25 Gm. of nitrogen daily. No clinical improvement was noted in spite of this high protein intake. I have recently carried out some experiments with benzoic and phenylacetic acid in order to gain some insight regarding some phases of intermediary protein metabolism. As a result I have formulated a working hypothesis concerning the possible role of glutathione in creatine formation, also in certain mechanisms of detoxification and other aspects of metabolism. Owing to the expensiveness of the glutathione I have started some experiments in which the combination of the three amino acids that go to form the glutathione molecule (glycine, cystine and glutamic acid) have been fed. I hope subsequently to be able to carry out some studies with glutathione itself.

DR. MEYER SOLOMON, Chicago. I have under my management at present a woman aged 25, who has had the condition about six years and who was diagnosed as having hysteria about six years ago. She presents a typical picture, including regurgitation of fluids through the nose, and weakness of the neck, arm and leg muscles. One month ago, after reading the article of Dr. Edgeworth and her encouraging report, I put the patient on ephedrine and can report quite a remarkable change. I didn't tell her what she was getting. Many of these cases are early looked on as being of emotional etiology, especially if symptoms come on very suddenly or the patient falls down getting on a street car or going up steps, as this patient did. The theory is that the symptoms are due to a fear reaction and autosuggestion following a fall with trauma. I would however call attention to the fact that Dr. Moersch has stressed one should be sure that the condition is myasthenia gravis and not a psychoneurosis, because the therapy is different and if the condition is a psychoneurosis the patient will get well if he has faith and confidence no matter what treatment is given. It is necessary to be on guard not to diagnose a functional case as one of myasthenia gravis as well as not to diagnose an instance of myasthenia gravis as a functional type.

MURPHEE B. VISSCHER, PH.D., Chicago. With regard to Dr. Boothby's emphasis on the infectious element in the etiology of myasthenia gravis I wish to state that in creatine determinations in sixty subjects I have found in normal individuals a very considerable creatine output associated with the occurrence of infection of the upper respiratory tract. This was of a very short duration and was not found at other times.

I have found this consistently and feel that this creatinuria during a certain stage of the upper respiratory infection may be of interest in connection with this suggestion. Recent knowledge regarding the function of creatine in muscle metabolism particularly in its relation to the diffusibility of the creatine complex in muscle has not been taken into account. It has been known for twenty years that creatine diffuses out of muscle only after the muscle is fatigued. The creatine in muscle is in an indiffusible state in resting muscle and it is only in the fatigued muscle when the creatine phosphate is broken down into creatine phosphoric acid that creatine can diffuse out. It seems likely that a defect in the rebuilding of creatine phosphate from creatine and the other precursor is of more importance than anything else in the creatinuria of these conditions. Certainly if the creatine were present as creatine phosphate it could not diffuse out. The influence of the ephedrine may be linked up with this mechanism. It is well known that epinephrine and other sympathetic stimulation either direct sympathetic or pharmacologic will accelerate the recovery process in muscle which is essentially the rebuilding of creatine phosphate from creatine and phosphoric acid. In this picture one sees the importance of accelerating the recovery process the resynthesis of creatine phosphate and one wonders whether the therapeutic problem is not directly related to this phenomenon.

DR M. H. NATHANSON, Minneapolis. There is little doubt that the amines related in structure to epinephrine including ephedrine, have the same pharmacologic actions. I felt that I demonstrated this in the paper I presented on the action of epinephrine-like compounds on the heart. The differences are largely quantitative. In view of the similarity in the physiologic action of epinephrine and ephedrine would it not be possible to apply in acute therapeutic test with epinephrine in cases of myasthenia gravis? Epinephrine could be administered in an effective dose and dynamometer tests used to determine whether there is any increase in muscular strength. In regard to ephedrine there appears to be a tremendous variation in the susceptibility of different individuals. It is possible that the drug is at times discarded before a sufficient dosage has been administered. It might be of value to test patients who are receiving the drug with some simple reactions as the blood pressure response, to determine whether they are actually having a systemic effect from the drug.

DR J. H. CLARK, Philadelphia. Our purpose in doing muscle biopsies and in studying them chemically and histologically is to try to determine what is taking place in the muscles. Just as kidney function is determined by blood analyses so we thought muscle analyses would tell what is happening in muscles under glycozell therapy. We do feel that there is a change and for the better but we have been somewhat disappointed in the clinical results obtained in the majority of our cases. We now have patients on occupational therapy to determine whether it will help reeducate muscles.

DR WALTER M. BOOTHBY, Rochester, Minn. Epinephrine has been frequently tried in myasthenia gravis without proving of any definite value. Dr. Edgeworth tells me that at various times it was tried out with her, and in none of the trials did she receive any benefit, her impression was that it made her worse. My experience is not yet sufficiently large to justify any definite conclusion, but I have the impression that the patients who were first started on glycine and kept on that several weeks before starting ephedrine did better than those who had been taking ephedrine a long time before starting glycine. I wish particularly to call attention to the danger of giving too much ephedrine and concur in Dr. Edgeworth's warning on this point (THE JOURNAL, May 6, 1933, p. 1401). I wish to thank Dr. Edgeworth and Dr. Guyton for especially coming to this meeting to make their own reports.

Vitamins Manufactured by Animals.—The vitamins were originally believed to be manufactured only by plants and not by animals, but this view can no longer be accepted. Vitamin A can be made by animals from its precursor carotene, a yellow pigment which is widely distributed in the plant world.—Colwell, S. J. *Vitamins in Clinical Medicine, Practitioner* 132:15 (Jan.) 1934.

VALUE OF SILVER ARSPHENAMINE IN THE TREATMENT OF EARLY SYPHILIS

CONCLUSIONS BASED ON A STUDY OF 104 CASES

A. BLANSON CANNON, MD

NEW YORK

Although approximately 200 patients with primary and early secondary syphilis have been under treatment with silver arspenamine at the Vanderbilt Clinic since June, 1931, some have been there for less than six months many have failed to return after a few times and others have been transferred, thus, on only 104 of the 200 patients are there data complete enough to include in this report. All of the patients had primary or early secondary lesions.

Observations of the time required for the disappearance of the spirochetes from the initial lesion after treatment was instituted were made on 12 of the 104 patients. The time necessary for the healing of the primary lesion, the disappearance of secondary lesions and the behavior of the Wassermann reaction were studied in the remaining ninety-two patients and the number and the types of complications were tabulated. The number of injections and the total amount of the drug necessary to bring about these changes were also calculated, the results being compared with those obtained with old arspenamine and with neo-arsphenamine.

ROUTINE TREATMENT

The ideal routine treatment at the clinic is to give each patient at least three courses of 10 injections each of silver arspenamine but every physician knows the

Fig. 1—Average time and treatment required for healing of primary lesions.

difficulty of getting patients, especially those who attend a clinic to adhere to a regular schedule. With men the initial injection is usually 0.15 Gm, the amount being gradually increased so that the last 4 injections will be 0.3 Gm each. With women, the initial injection is usually 0.1 Gm and the amount is gradually increased to 0.25 Gm. With the first course of arspenamine, 15 injections of an insoluble mercury or bismuth preparation are given at intervals of from five to seven days followed by alternate courses of arspenamine and a mercury or bismuth preparation so that each patient will receive at least 30 injections of silver arspenamine and 45 of a mercury or bismuth preparation without interruption.

From the Vanderbilt Clinic, Columbia University College of Physicians and Surgeons.
Read before the Section on Dermatology and Syphilology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

HEALING OF LESIONS

Primary Lesions—The records in twenty-four of the cases showed that it required as short a period as 2 days and as long a period as 49 days from the initial treatment for the primary lesions to heal the average being 20.92 days. The patients had from 1 to 10 injections and from 0.1 to 2.35 Gm, making an average of 5 injections and 1.15 Gm of silver arsphenamine. The unusually long time that it took for some of the chancres to heal could be explained by the large size of the chancre and the presence of secondary infection.

Fig. 2—Average time and treatment required for healing of secondary lesions.

Secondary Lesions—In fifty-two patients with secondary syphilis with lesions of the skin and mucous membranes, it required from 2 to 63 days from the first dose of silver arsphenamine for the lesions to disappear, or an average of 16.08 days. The patients were given from 1 to 10 injections, or an average of 4.02. The number of grams received was from 0.15 to 2.7, an average of 0.765.

In this group, the secondary lesions recurred in one patient. This patient received treatment for three weeks, was absent from treatment for eighteen weeks, and then received an additional two and one-half weeks' treatment followed by a second lapse of sixteen weeks. He had had a total of only 8 injections. The relapse in this case makes the figure for clinical relapse in this group 1.9 per cent.

WASSERMANN REACTIONS

Primary Cases with Negative Serologic Tests—There were thirteen primary cases in which the serologic tests were negative, the diagnosis being established in each instance by positive observations on dark-field examination and by the clinical appearance of the initial lesion. While the Wassermann reaction was negative in all thirteen cases when treatment was begun, it remained so in only two cases. It has continued to be negative in these two to date, a period of twenty-six and forty-four weeks, respectively. Of the remaining eleven the Wassermann reaction became slightly positive (plus-minus) in five, later becoming negative and continuing so in three of the five and fluctuating between negative and plus-minus in the other two. A strongly positive Wassermann reaction (4 plus) developed in the other six patients, in three of these the reactions became negative and have persisted so, in two they fluctuated between negative and plus-minus, and in one the reaction has remained strongly positive to date.

For the purpose of this paper I have classified as positive all Wassermann reactions with a reading of from 4 plus (strongly positive) to 2 plus in both antigens (moderately positive). The term plus-minus (slightly positive) includes those cases with a 1 plus

reaction in both antigens and from a 4 to 2 plus reaction in one antigen and 1 plus or negative reaction in the other antigens, and the term negative, those cases with a 1 plus reaction in one antigen and a negative reaction in the other or negative reactions in both antigens.

Cases with Positive Serologic Tests—The records on eleven primary cases in which the serologic tests were positive showed that from 24 to 103 days after the first treatment were required to produce negative Wassermann reactions, with an average of 59.81 days. The patients in this group received from 8 to 17 doses and from 0.85 to 3.95 Gm, the average being 2.17 Gm of the drug and 10 injections.

In five cases there was a reversal of the negative Wassermann reactions from nine to fifty-six weeks after treatment was begun. In four, the reaction was only slightly positive (in three cases with a 2 plus reaction in the alcoholic antigen, in one case, a 2 plus reaction in the alcoholic antigen and a negative reaction in the cholesterol antigen). In the fifth case there was a relapse to strongly positive in both antigens, after the patient had been absent from treatment for three different periods of from six to nine weeks each.

In addition to the eleven primary cases in which the serologic tests were positive, there were three in which a complete reversal of the positive Wassermann reaction did not take place. Two of these patients were treated regularly for thirty-one and twenty-eight and one-half weeks respectively, one receiving 4.2 Gm of silver arsphenamine in 18 injections, and the other 3.3 Gm in 19 injections. The third received 9 injections, was absent from treatment for twenty-three weeks, and then had 9 more injections. He was given a total of 4.35 Gm in 18 injections. In the first and third cases, the serum remained 4 plus in both antigens of the Wassermann reaction while in the second it showed a 4 plus reaction in the cholesterol antigen only.

Fig. 3—Average time and treatment required for the Wassermann reaction to become negative in primary cases in which the serologic test is positive.

Secondary Cases—There were sixty-five cases of secondary syphilis, and of this number, negative Wassermann reactions were obtained in fifty-five within from 32 to 362 days after the beginning of treatment with silver arsphenamine the average number of days being 112.89. The number of doses required ranged from 4 to 38, averaging 11.02 injections, the number of grams each patient received varied from 0.65 to 9.10, an average of 2.51.

Of the fifty-five cases in which negative Wassermann reactions were obtained, a serologic relapse occurred in

twenty-one In sixteen of these the relapse was slight, the reaction being only 2 plus in the cholesterol antigen and negative in the alcoholic antigen in eleven cases, 3 plus in the cholesterol antigen and negative in the alcoholic antigen in two cases 2 plus in the alcoholic antigen and negative in the cholesterol antigen in one case and 3 plus in the cholesterol antigen and 1 plus with the alcoholic antigen in two cases In the remaining five of the twenty-one cases in which relapses occurred there was a reversal of the negative Wassermann

Fig. 4—Average time and treatment required for the Wassermann reaction to become negative in early secondary syphilis

mann reaction to 3 plus in the cholesterol antigen and to 2 plus in the alcoholic antigen in one and to 4 plus in both antigens in four cases The most recent Wassermann reactions obtained in twelve of the twenty-one cases were negative

In the ten of the sixty-five patients with secondary syphilis who did not obtain a complete reversal of their positive Wassermann reactions the reactions remained persistently 4 plus in four, and showed some lessening of intensity in the other six Of the four patients with persistently strongly positive Wassermann reactions one attended the clinic regularly for thirty-one weeks and then was absent and the other three were absent from eight to nineteen weeks after a few injections (from 4 to 6) Of the six cases in which there was some improvement in the Wassermann reaction the reaction in one came down to 4 plus in the cholesterol antigen and to 1 plus in the alcoholic antigen, in a second case to 3 plus in the cholesterol antigen and to 1 plus in the alcoholic antigen, in a third case to a 4 plus in the cholesterol antigen and to negative in the alcoholic

Fig. 5—Comparison by drugs of results based on the first negative Wassermann reaction and the serologic relapses

antigen, in the fourth and fifth cases to 2 plus in the cholesterol antigen and to negative in the alcoholic antigen, in the sixth case, to 2 plus in both antigens under silver arspenamine, later becoming negative with another drug

DISAPPEARANCE OF SPIROCHETES

It was only late in the study of the problem that repeated examinations were made of the primary lesions for the time required for the disappearance of spirochetes from the early lesions of syphilis, so that

only twelve cases could be included in this group This phase of the problem did not appear to be important because of the difficulty so frequently experienced in finding the spirochete after repeated examinations even in untreated patients

From the twelve patients with early lesions in which spirochetes were demonstrated it was found that an average of 3.91 days, of 2.37 injections and of 0.35 Gm was required for the disappearance of the spirochetes

SPIRAL FLUID EXAMINATION

A lumbar puncture was performed on 39 of the 104 patients under observation Seven showed a positive serologic test two having only moderately positive reactions with 2 cc with a slightly increased globulin and a syphilitic colloidal gold curve The other five patients had strongly positive Wassermann reactions in a 0.5 cc dilution two with a positive syphilitic colloidal gold curve and an increase in the globulin One of the patients with a mildly positive reaction showed a negative reaction after further routine treatment while the other patient was transferred to another clinic One of the patients with a strongly positive reaction also showed an entirely negative reaction on additional routine treatment the other four patients with strongly positive reactions had only recently undergone spinal puncture and are continuing under treatment One of these patients with a strongly positive Wassermann

membranes. The majority of the cases were of a mild type. In one instance the icterus was marked, lasting twenty-eight weeks, with an exacerbation during a mastoiditis for which operation was performed under ether anesthesia. The jaundice appeared after an average of 133 injections, but in some instances after as few as 4 or as many as 32 intravenous injections. The patients had received on an average of 296 Gm. of silver arsphenamine before the appearance of the jaundice. In some instances the icterus was noticeable after as little as 0.9 Gm. of silver arsphenamine, although one patient had been given as much as 5.5 Gm. before an icteric change was detected in the skin and mucous membranes. The jaundice appeared on an average of 147.6 days after treatment was instituted, the shortest length of time was 69 days and the longest 242. The presence of jaundice was noticed from 1 to 133 days following the last intravenous injection, or an average of 42 days. In two instances the jaundice was preceded by dermatitis and in these two cases the symptoms were very mild and lasted only about two weeks.

There were no cases of generalized exfoliative dermatitis in the group of patients treated with silver arsphenamine, although eight patients did have the eczematoid or scarlatiniform variety. All had a mild type, and no patient was sufficiently ill to require hospitalization. In most instances the treatment with silver arsphenamine was resumed after a short rest period, during which the patient was receiving a mercury or bismuth preparation. Those who showed cutaneous complications had received from 4 to 13 injections, or an average of 7.75, with an average of 1.50 Gm. of silver arsphenamine, the lowest amount being 0.65 Gm. and the highest 2.65. These patients had been under treatment from 12 to 133 days before the dermatitis was noted. The dermatitis appeared as early as 1 day after the last injection and as late as 6 weeks, making an average of 10.9 days from the last treatment with silver arsphenamine.

The ratio of the number of reactions to the total number of patients was 1/4, while the ratio of mild complications to the total number of injections given was 1/129, and that of the severe and delayed combined, 1/88.

PATIENTS OBSERVED MORE THAN ONE YEAR

Forty-four of the group of ninety-two patients were treated and observed for over a year, the average length of time under active treatment being 68 weeks, the shortest 24, and the longest 167 weeks. Eight of these patients were observed for an average of forty weeks after suspension of treatment. The average for both observation and treatment was seventy-five and one-half weeks. This group of forty-four patients received an average of 25.91 injections, and 5.99 Gm. of silver arsphenamine. The highest number of injections was 62.5, and the greatest number of grams to an individual patient was 14.55. Fifteen of the patients have been given over 7 Gm. of silver arsphenamine, and to the present time no one has shown any evidence of an argyria. Only three of these patients received over 40 injections of silver arsphenamine.

Twenty-one patients in this group observed for over one year had a relapse of the Wassermann reaction, sixteen to plus-minus only (less than 2+ in both antigens) and five to strongly positive, or 4 plus. The last Wassermann reactions in sixteen cases were negative. Seven of the twenty-one patients showed more than one relapse of the Wassermann reaction. Twelve

patients in this group had complications, eight having immediate reactions and six delayed reactions. (Two patients had dermatitis, four had icterus.)

ARGYRIA

During the past two years, following extensive treatment with silver arsphenamine in the clinic, four patients have been observed with the typical slate blue-gray pigmentation of the skin seen in persons with argyria. Three were from the Vanderbilt Clinic and one had been treated in another department and transferred to the dermatologic service. The pigmentation was noted after an average of 75 injections (40, 82, 68 and 100) and 12.57 Gm. of the drug (7.35, 16.40, 10.95

Argyria Following Use of Silver Arsphenamine

Description of pigmentation	Case 1	Case 2	Case 3	Case 4
	Skin and mucous membranes a distinct slate gray	Skin and mucous membranes a slate gray	Skin of head and neck a slate gray	Skin and mucous membranes a slate gray
Age at onset	64 years	52 years	5 years	52 years
Sex	Male	Male	Male	Male
Race	Hungarian	Irish	Pollak	Italian
Amount of silver arsphenamine received	7 Gm.	16.40 Gm.	10.95 Gm.	1.6 Gm.
Number of injections	40	82	68	100
Length of treatment with silver arsphenamine	3 1/2 years	9 1/4 years	4 years	4 1/2 years
Interval from last treatment to onset of argyria	11 1/2 months	1 month	10 days	1 1/2 months
Duration of syphilis on admission	40 years	18 years	22 years	2 1/2 years
Wassermann reaction on admission				
Blood	+	—	+	—
Spinal fluid	+	+	+	—
Diagnosis on admission	Tuberculous dorsalis optic atrophy right eye	Tuberculous dorsalis optic atrophy right eye	Tuberculous dorsalis optic atrophy right eye	Demential paralysis
Treatment previous to admission	72 injections of arsphenamine 17 of mercury	15 intravenous injections 7 intraspinal injections	None	70 injections of arsphenamine 50 of mercury
Other drugs after admission				
Mercury	6	2	10	5

Others	8 injections of trypan blue	28 injections of arsphenamine	0	20 injections of arsphenamine
Spinal treatment	8	2 1/2	10	8

and 15.6 Gm.) They had received treatment for an average of 5 years (3 3/4, 9 1/4, 4 and 4 3/4 years). Their ages were 64, 52, 55 and 53, respectively. The pigmentation was most marked in the oldest patient—the one who had received the smallest amount (7.35 Gm.) of silver arsphenamine and fewest number of injections (40) over the shortest period of time (3 3/4 years).

The pigmentation was noted within a month and a half after the last injection of silver arsphenamine in three cases, and after thirteen months in the fourth case. Three patients received an average of 63.3 injections of a bismuth preparation. Three received from 2 to 10 injections of mercuric salicylate. The fourth patient had two injections of a mercury preparation only, but no injections of a bismuth preparation.

It is evident from the clinic records of persons treated with silver arsphenamine that argyria should

be borne in mind as a possible complication in all persons treated with that drug, especially in older people receiving repeated injections over a long period of time. It is significant that all four of the cases of argyria were in men who were 50 and over, each one of whom was also suffering with neurosyphilis. Three had optic atrophy, especially marked in the right eye, and tabes dorsalis, while the fourth had dementia paralytica. That argyria is an infrequent complication (especially in younger subjects) following medication with silver arsphenamine is evidenced by the rarity with which one sees or hears of the condition. Of the many patients treated with silver arsphenamine at the clinic since 1919, there are records of only the four cases of argyria, and so far as can be determined only nine have been thus far reported in medical literature following treatment with this drug. Two of the patients have shown a marked decrease in the intensity of the pigmentation after a year's treatment with sodium and

disappeared more rapidly with a fewer number of injections and a smaller total of grams of silver arsphenamine than with neoarsphenamine. In the primary cases with positive serologic tests the average time for the Wassermann reaction to become negative was shorter, with fewer injections, and with a smaller amount in grams than with neoarsphenamine. The same was true of secondary cases except that the average time in days required for the Wassermann reaction to become negative was approximately the same for both neoarsphenamine and silver arsphenamine, the time being 113 and 112.89 days, respectively.

COMPARISON OF COMPLICATIONS FOLLOWING THE ADMINISTRATION OF THE THREE ARSPHENAMINES

On comparison of the complications that arose following the administration of silver arsphenamine with those tabulated after treatment with old arsphenamine

Fig. 7—Cases of argyria. A patient P. O. T. aged 52 who was given 16.4 Gm. of silver arsphenamine in eighty-two injections. B patient aged 55 who was given 10.95 Gm. of silver arsphenamine in sixty-eight injections. C patient H. B. who had argyria following several years' use of mild silver protein.

calcium thiosulphate given intravenously and by mouth. One patient with argyria following long use of mild silver protein has also shown a decided lessening in the intensity of the pigmentation under the same treatment.

COMPARISON OF STATISTICS WITH THOSE OBTAINED WITH OLD ARSPHENAMINE AND NEOARSPHENAMINE

On comparison of the records of the ninety-two patients with primary and early secondary syphilis who received silver arsphenamine with the records of others treated in a like manner with old arsphenamine and with neoarsphenamine, it was found that silver arsphenamine, while decidedly less efficacious than old arsphenamine, is in most respects superior to neoarsphenamine, as can be seen from the study of the charts.

In the primary cases with negative and positive serologic tests, a fewer number of injections of silver arsphenamine, a smaller amount of the drug and a slightly shorter length of time were required to cause the initial lesion to disappear, than was the case with neoarsphenamine. Even the secondary lesions

and with neoarsphenamine, it was observed that silver arsphenamine showed slightly to advantage over the other two in immediate mild reactions, the ratio being 1.8 for silver, and 1.7 for both old arsphenamine and neoarsphenamine. There were no severe reactions with old arsphenamine, while the ratio was 1.53 with neoarsphenamine and 1.33 with silver arsphenamine. The best showing is made with old arsphenamine and the next best with neoarsphenamine, but, it is only correct to state that the delayed reactions after silver arsphenamine were of a much milder character than those following injections of neoarsphenamine. There was not a single case of generalized exfoliative dermatitis after injections of silver arsphenamine, and only one of severe jaundice, that patient having had an exacerbation during an acute mastoiditis and having been operated on under a general anesthetic (ether). Perhaps silver arsphenamine may have an advantage over old arsphenamine and neoarsphenamine in that there is a smaller quantity of arsenic present in each dose—about half the amount of the arsenic in the other two drugs.

From the study of the comparative values of old arsphenamine, neoarsphenamine and silver arsphenamine, I believe that old arsphenamine is proving itself to be the most efficacious remedy, and first choice for the treatment of early syphilis and that silver arsphenamine seems to be in practically every respect, superior to neoarsphenamine. The technic in the administration of silver arsphenamine is just as simple as is that of neoarsphenamine, and it further has the advantage of not possessing the toxic sulphur radical contained in neoarsphenamine and in neosilverarsphenamine.

For the past three years in private practice, I have used old arsphenamine exclusively, except in a few selected cases in which silver arsphenamine was administered. I have given no neoarsphenamine.

In the clinics and hospital with which I am connected, only old arsphenamine and silver arsphenamine are now used.

The greatest objection to the general use of old arsphenamine has been the complicated technic of giving it. While I still advocate administering all arsphenamines by the gravity method and well diluted I have for many years treated syphilitic infants and adults with very small veins by the syringe method with a hypodermic or small needle using old or silver arsphenamine. I have only recently given the fortieth intravenous injection of old arsphenamine to an infant under 1 year of age, injecting the drug into the scalp veins without experiencing the slightest difficulty. Now that the manufacturer of arsphenamine dispenses with each ampule of the drug an ampule of distilled water and another of sodium hydroxide sufficient to alkalize the solution (also litmus paper to test the alkalinity), there can be little reason for not using the most effective antisymphilitic remedy, which I have no hesitancy in saying I believe to be old arsphenamine.

ABSTRACT OF DISCUSSION

DR EARL D. OSBORNE, Buffalo. For several meetings new preparations have been suggested for the treatment of syphilis. If I should give the one reason why silver arsphenamine is not more popular I would say it is fear of the development of argyria. Dr Cannon has honestly pointed out that he has had four cases in a long series in several years' use of this drug. I have not had any cases. I did not get from Dr Cannon what his dosage is over any period of time whether he gives 0.3 Gm every week or 0.3 Gm every five to seven days. European observers have pointed out that the maximum total dosage within the safety limit equals from 7 to 9 Gm. Analysis of the charts of Dr Cannon shows that with the exception of the one old man, the other patients received considerably in excess of the accepted standard of safety with regard to argyria. I have not had any cases, for I have kept the total dosage below 9 Gm. Dr Cannon has justified the observation that the sheet anchor in the treatment of syphilis is arsphenamine. Analysis of his charts shows that the serologic relapses surpass those of sulpharsphenamine. When I cannot use arsphenamine I use neoarsphenamine. Dr Cannon produced effects with silver arsphenamine comparable to those produced with arsphenamine or neoarsphenamine. The late effects such as jaundice are closely connected with the late effect of the metabolism of arsenic in the liver. I wonder whether bismuth compounds were used along with it or whether the patients had previously had arsphenamine or neoarsphenamine. The mere finding of larger amounts of silver arsphenamine in the spinal cord does not mean that it is more effective than any other. That applies to some of the newer drugs as well. As to the combination of silver arsphenamine with heavy metals such as bismuth I have made it a rule to cut the dose of bismuth at least one third for after all one is using two heavy metals and I think Dr Cannon's results were perhaps due to too much heavy metal.

DR A. B. INSON CANNON, New York. I made it a rule to give men from 0.1 to 0.3 Gm of silver arsphenamine, usually beginning with the smaller amount and gradually increasing so that the last four injections were of the maximum dose. A course of ten injections was prescribed, followed by mercury or bismuth compounds at intervals between the courses of silver arsphenamine. In women the doses were somewhat less, the maximum being usually 0.25 Gm. As my purpose was to compare the results from the use of silver arsphenamine with those that I had obtained with arsphenamine and neoarsphenamine, I selected only patients with primary and secondary lesions who had not received any previous treatment. I was surprised by the number of cases of jaundice I had, but, as I remarked, only one of the cases presented a severe type of icterus and that might be explained by the patient's having been operated on for an acute mastoiditis. I make a bile index on each individual receiving treatment and any patient showing an icteric index of 15 or more was counted as a case of jaundice whether or not there was any noticeable change in the color of the skin or sclera, a fact that might in part account for the large number of cases of jaundice I had in the series of patients treated with silver arsphenamine.

MODERN TREATMENT OF BRAIN ABSCESS

HARRY P. CAHILL, MD

BOSTON

Success in the treatment of brain abscess rests on a tripod of medical actions: first, a correct diagnosis; second, proper operative methods; and third, rational after-treatment.

It is a simple procedure to state the characteristic signs and symptoms of frontal temporo-sphenoidal or cerebellar abscess formation. When, however, increased intracranial pressure, spreading cerebral edema or localized meningeal sepsis jumble the entire abnormal picture into a jigsaw puzzle of contradictions, a clear mind with balanced judgment is most vital. When the symptoms of temporo-sphenoidal or cerebellar abscess are clear and distinct, the diagnosis may be definite. When the converse is true, a carefully taken history may be the determinant of success.

The characteristic focal signs of brain abscess may be absent, and the diagnosis of the condition rest entirely on the presence of general signs and symptoms of intracranial abscess formation. Here, drowsiness with a history of vomiting may clear away the fog of uncertainty resulting from the associated secondary meningitis.

The presence of sinus thrombosis always points to the posterior fossa as the probable site of the brain lesion. In all cases of sinus thrombosis, aseptic torcular or even aseptic cavernous sinus thrombosis resulting from progressive extension of the thrombus may produce signs and symptoms due entirely to obstruction of the cerebral venous flow. In all cases of this kind, extension of the sterile distal end of the clot to the torcula or even to the cavernous sinus may produce signs and symptoms of severe intracranial pressure. Two cases of this type in which the distal extension of the thrombi remained sterile and produced marked venous obstruction are worthy of consideration.

REPORT OF CASES

CASE 1.—L. S., a girl, aged 9, was admitted to the Massachusetts Eye and Ear Infirmary on Jan. 28, 1927. Four weeks

Read before the Section on Laryngology, Otolaryngology and Rhinology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

before admission she had a cold in the head with pain and discharge in the left ear. A simple mastoidectomy was performed two weeks later followed in two days by jugular ligation on the left side. Within the next week signs of increasing intracranial pressure appeared including changes in the fundi, vomiting and bilateral paralysis of the external rectus muscles.

On admittance to the Massachusetts Eye and Ear Infirmary, the middle ear was dry, and the mastoid and jugular wounds were completely healed.

The patient had bilateral palsy of the external rectus muscles and slight facial weakness on the right side. A pupil edema of 4 D in the right eye and 6 D in the left eye was present. The fields of vision were normal and vision was 15/20 in each eye. The spinal fluid was normal on examination, but was under a pressure of 700. The pressure was reduced one half and repeated punctures were made every forty eight hours for two weeks and then every four days for another fortnight. On March 16 the pressure had remained at 150 for two weeks and all the symptoms had entirely cleared up. The papilledema and palsy were no longer present and the fields of vision were normal.

CASE 2.—Lewis T. aged 15 was admitted to the Massachusetts Eye and Ear Infirmary on Sept. 30, 1932 complaining of pain in the left frontal region and tenderness of the left parotid gland with slight increasing exophthalmos of the left eye and edema of the left conjunctiva for the past two days. The onset of the present illness was Sept. 16, 1933 when the patient complained of severe pain in the right frontal region and right nasal pain accompanying a slight cold in the head. Within twenty-four hours a purulent discharge appeared in the right ear and persisted to date. During the night of September 22 the pain became very severe, and the patient vomited several times. The temperature was 100 F. The following day the patient was drowsy and entered the local hospital.

During the next six days the patient vomited twice daily, usually accompanied by nausea and the temperature was septic ranging from normal to 103.6 F. On September 27 the pain in the frontal region had developed into a general headache which later localized in the left side of the head and finally in the left eye. During this time the white blood count ranged between 9,400 and 11,600. The spinal fluid on two occasions was practically normal.

A simple bilateral mastoidectomy had been performed in June 1925 following scarlet fever and a secondary operation on the left mastoid two and one half years later. Neither ear had discharged during the past twenty months. When the patient entered the Infirmary on September 30 the white blood count was only 10,700 with 74 per cent polymorphonuclears and 24 per cent lymphocytes. The blood culture showed no growth in forty hours, and the spinal fluid examination gave entirely negative results except that the Ayer-Tobey test appeared to show a slight partial block of the right jugular vein. Examination of the eye by Dr. Frederick Verhoeff showed ptosis and slight exophthalmos of the left eye, with limitation of motion outward and upward.

The patient had a septic temperature for a week but it was accompanied by marked improvement in the condition of the eye and a constant decrease in both the white blood cells and the polymorphonuclear count. On October 13 the temperature had been normal for five days, and the chemosis and ptosis of the left eye had nearly disappeared. There was little if any limitation of motion in either eye. The discharge from the right ear had practically cleared up. There was still some blurring of the left disk. The patient was discharged to his home on November 2.

DIAGNOSIS

The diagnosis of abscess of the frontal lobe is still in the "dark stages." Edema of the upper eyelid and of the tissues over the frontal sinus points to osteo-thrombophlebitis of the underlying bone. Hence osteomyelitis of the skull and frontal lobe abscess are distinct possibilities. The presence of such edema in an acute infection of the frontal sinus, coupled with

headache, slow pulse and vomiting, suggests involvement of the frontal lobe. The additional signs of drowsiness, euphoria, convulsions and contralateral central facial paralysis with or without weakness of the arm fix that diagnosis. Edema over an infected frontal sinus is equal in importance to edema over the emissary vein in mastoiditis. It is an indication of thrombophlebitis of a neighboring vessel. It is announcing the presence of osteomyelitis or brain abscess or both. Repeated roentgenograms will rule out a diagnosis of osteomyelitis and if edema appears about a week after the onset of the infection of the frontal sinus, or if a periosteal abscess is found, it is of more serious concern. In such cases the posterior wall of the frontal sinus should be carefully examined and removed. The discovery of an extradural frontal abscess practically announces the presence of an accompanying abscess of the frontal lobe. In several of the cases of frontal lobe abscess at the Infirmary the inner frontal wall of the frontal sinus was intact yet not only was the dura affected, but a fistula was present.

When abscess formation is present in the left temporosphenoidal lobe of right-handed persons and vice versa, a sound memory aphasia may be present. When such an abscess develops in a silent temporosphenoidal lobe a quadrantic homonymous hemianopia, or a contralateral hemiparesis or lower facial weakness may determine the diagnosis. Paralysis of the orbicularis oris of hypoglossal origin can easily be differentiated from that of the central facial type.

A nonreacting labyrinth with signs or symptoms of intracranial involvement also favors the diagnosis of a subtentorial lesion. If headache and increased temperature without pain in the retro-orbital region occur during convalescence after complete exenteration of the mastoid in a person with a nonreacting labyrinth any of five types of inflammation of the posterior fossa is possible.

Empyema of the saccus endolymphaticus, infection of the lateral cistern and localized arachnoiditis are difficult to differentiate. Their definite reaction is a localized meningitis. When a definite diagnosis is unattainable the method of procedure used at the Infirmary should be considered. The area of the saccus and the medial cisterna is explored. If a focus of active infection is not obtained the study of the patient's general appearance, temperature curve, white blood count, spinal fluid picture and reflex response will usually point out the source of the inflammation. The dull stuporous patient with cerebellar abscess, with eyes deviated away from the lesion, lying curled up in the bed contrasts sharply with the anxious irritable meningitic patient, or with the bright, animated thrombotic patient. The normal or subnormal temperature curve of the person with brain abscess is as characteristic as the continually high temperature level in meningitis or the saw-tooth septic form in cases of infected sinuses. The very high white blood count singles out spreading meningeal suppuration from the other two lesions. The spinal fluid picture and the reflex responses of the same lesions have similar distinct marks of differentiation. The caloric test will not only inform one of the viability of this labyrinth, but will at times differentiate between supratentorial and subtentorial lesions. The presence of severe vertigo and vomiting after labyrinthine stimulation always favors a diagnosis of supratentorial involvement. Abscess of the frontal and the temporosphenoidal lobe may contain gas. This is demonstrable by roent-

genograms and localizes the abscess. The gas is always under pressure equal to the intracranial pressure, hence when it escapes through the exploratory needle, it usually fills the operating room with its fetid odor. Air can enter a capsulated abscess after exploration, and at times leaks into the subdural space.

TREATMENT

Injection of iodized poppy seed oil 40 per cent has its place in the after-treatment of the capsulated abscess. In recent or noncapsulated brain abscess there is danger in its use. At the Infirmary, therefore, it has been reserved for those cases which have not progressed favorably. If headache with increased temperature or other questionable sign or symptom of imperfect drainage appears, its use may make clear that the drain is not in proper position and is outside the capsular wall. Thus it is a gage of the success of the drainage of the abscess. It has shown in several cases how easily recurrence can be favored by imperfect collapse of the abscess walls and thus demonstrates that at least many of the cases of multiple otitic brain abscesses are satellitic in origin. Apparently the capsulated abscess wall tolerates it. Roentgen evidence of a residue of iodized oil in the capsule of an apparently healed brain abscess has been seen years after the injection.

Capsulated brain abscess is found most frequently in the temporal lobe. Abscesses of the frontal lobe have in many cases a thick lining membrane. Both acute and chronic primary infection may give origin to the formation of brain abscess without any lining membrane, the so-called noncapsulated abscess. Acute cerebellar abscess is rarely capsulated. The treatment of the noncapsulated abscess with its walls of infected and necrotic brain tissue has not been satisfactory. The capsule of the abscess is important not only as a barrier against extension directly, but indirectly through the vascular or perivascular route.

The use of the filiform drain, the Lemaitre method, has been successful in one of the cases at the Infirmary. In other cases, results were satisfactory for a time and then extension or insufficient drainage occurred. Capsular formation in these cases was not a question of time only. Other factors must play an important part in such localization. Deep abscesses will always have a much higher mortality than the superficial type. Complete collapse of the walls of the abscess, as shown by injection of iodized oil is of favorable omen.

The ordinary procedure at the Infirmary is reviewed in the hope of stimulating its improvement.

In cases of acute frontal sinusitis with probably frontal lobe abscess a vertical incision in the median line joining the horizontal Kilian incision enables the scalp to be sutured back exposing the frontal bone. The anterior bony wall of the frontal sinus is then removed. The posterior wall of the frontal sinus is always carefully examined for exposed dura. The posterior wall of the sinus and adjoining frontal bone is then removed. In about 50 per cent of frontal lobe abscesses, diseased dura or a small dural fistula is present. The tip of a small, number 14 catheter is gently inserted for drainage and immediate relief of pressure symptoms. Either of two methods of after-treatment is now possible. The first method includes the dilation of the fistula every forty-eight to seventy-two hours by the insertion of a suitable larger catheter until a number 24 catheter drain is accepted. Several persons have recovered with such treatment only. In other cases it

was hoped that the time element might be thus obtained for capsular formation. In the latter type and in frontal lobe abscess adjacent to a chronic involvement of the frontal sinus the removal of a cone of cerebral tissue reaching to the capsular wall by means of the radio knife and loop of Bovie has been the method employed. It permits the use of the larger size of the Mosher wire gauze drain. The drain can be placed more accurately with little trauma or hemorrhage.

It is safer to enclose the exposed dura with diathermy. A crucial incision is made in the dura to ascertain whether a superficial abscess or flat arachnoid lake is present before exploration is done for a deeper abscess. When the wire drain is suitably placed, various aids, such as rotation of the head, gravity, lowering of the top of the table and suction, may be employed to assist the cerebral pressure in promoting drainage and obliterating the abscess cavity. The formation of a fistulous tract about the drain to the abscess cavity makes the capsular wall extend to the surface of the brain. Thus the method used at the Infirmary approaches in a degree the unroofing operation of King. The drain, if in proper position is allowed to remain undisturbed for about four weeks. The scalp sutures are then removed and the brain permitted to expel the drain gradually. During this period of drainage, little trauma due to manipulation of the drain is transmitted to the walls of the abscess. Hence, the chance of extension of infection through venous thrombosis of the capsular wall vessels is greatly lessened.

In abscesses of the temporosphenoidal lobe, approach through a subtemporal decompression has grown greatly in favor. In moribund patients with a sclerotic mastoid, it is the best method. An extended approach through the mastoid has given the highest average of recoveries. Here as in frontal lobe abscess, granulations on the dura or exposed dura guide one to the meningeal or intracerebral abscess in over 50 per cent of cases. Here the meninges are well walled off. Here a fistulous stalk opens at times. Here, the abscess is frequently near the cortex.

In the treatment of cerebellar abscess as in abscess of the middle fossa, there is some question as to the avenue of approach. If symptoms or signs of labyrinthine involvement preceded those of cerebellar infection, the paramastoid route through Trautmann's triangle, with at times obliteration of the lateral sinus, must be considered. When the abscess is secondary to involvement of the sinus, drainage through the inner wall of the sinus has been the customary procedure at the Infirmary. Examination of the inner wall of the sinus may demonstrate a possible lead or a thrombosed plug in a small venule. If exploration of the mastoid cells posterior to the sinus reveals the presence of an extradural abscess, this area of protective meningeal adhesions should be used.

The importance of deciding which of these three avenues has a given area of meningeal protection may mean the difference between success and meningitis.

There is in the school of the present day one group favoring larger and larger drainage openings while another is using repeated puncture and suction. Rubber drains of fine caliber are favored by the latter group.

The ideal treatment of a brain abscess would be to remove it in toto. This has been successfully accomplished but the surgical shock, the encephalitis, the hemorrhage and danger of infection from the stalk, if present or from the diagnostic puncture or from rupture of the capsule, are insurmountable obstacles in the

way of its success. Hemorrhage into the operative cavity may account for the sudden death in these cases weeks after an apparently successful convalescence. Partial removal of the wall of the abscess by unroofing it with herniation, greatly decreases the danger of the removal in toto.

The Dandy method of repeated tapping of the brain abscess has many points in its favor. It relieves the excessive intracranial pressure for a time and hence furnishes the time factor necessary for proper capsulation of the abscess. One must be open-minded and let the emergency guide the course. All drainage is for the purpose of emptying the abscess cavity so that the intracranial pressure will obliterate it.

ABSTRACT OF DISCUSSION

DR ARTHUR W. ADSON, Rochester, Minn. It may not be amiss to reemphasize two phases of this subject: first, the surgical indications; second, the surgical treatment. In selecting the time to evacuate a brain abscess, one should remember that the condition is not unlike other inflammatory processes and that drainage is most effective when immunity has been established. Every brain abscess passes through three stages: the encephalomeningitic stage, encapsulation, and recovery or fatality. Recovery may take place spontaneously or by surgical drainage and death by rupture of the abscess into the ventricular system. During the first two stages, supportive measures are employed: rest in bed, nourishing diet, ice bags and cool sponges for fever, spinal drainage, and hypertonic solutions to control intracranial pressure. This period usually continues for two or three weeks. When encapsulation takes place, the septic temperature subsides, leukocytosis recedes to 12,000, neurologic symptoms likewise become less diffuse and those that remain suggest a localized cerebral lesion. If the spinal fluid cell count has been increased, it will also return to normal. Small abscesses have been known to heal spontaneously. The pus becomes inspissated and the capsule contracts to form a fibrosed mass. In evacuating an abscess, one must steel dependent drainage, with as little trauma to the brain as possible, and avoidance of surface contamination. This is accomplished by performing a small decompression over the abscess, fixing the meninges to the cortex with catgut sutures and electrical coagulation of the margins. The abscess is partially drained with a brain cannula, after which the capsule is incised along the cannula. The capsule is held with a bivalve speculum with lateral flanges to prevent the cortex from following away from the skull. The remaining pus is evacuated, the cavity is explored with an illuminated retractor, necrotic tags are removed and lateral pockets are thoroughly cleaned. Then two rubber tube drains and two strips of iodoform gauze are inserted; the gauze is picked loosely about tubes and into pockets to prevent sealing of recesses which might cause recurrences. The gauze picks prevent falling of the capsule and retraction of the brain from the skull. The gauze drains are removed slowly over a period of a week, allowing the capsule to contract and form a sinus around the tubes. The tubes are likewise shortened during the second and third weeks, thus permitting granulation and obliteration to take place from the dependent regions first. Sterile abscesses might be effectively drained by repeated aspiration, but even then recurrence can take place. Surgical recovery and prevention of recurrence are achieved by waiting for encapsulation and the development of immunity with thorough, adequate and continuous drainage.

DR R. EUSTACE SEMMES, Memphis, Tenn. The general principles to be followed in handling brain abscess, that is, waiting for encapsulation to take place, and adequate and sufficiently prolonged drainage with the least possible damage to the brain, do not seem to be open to debate. The difficulty arises when the demands of the patient, the abscess and the brain conflict. An abscess may be present in a lobe of the brain without giving local signs. Whether an abscess is present at all is frequently doubtful. It is necessary therefore to employ the simplest method, in the beginning at least. For

this reason I have adopted the plan of making only a perforator and burr opening under local anesthesia, removing a small circle of dura with the electrocoagulation needle, through which a blunt ventricular needle is inserted. When the abscess capsule is encountered and its depth is measured, the point is pushed in and the needle is allowed to drain into a glass tube connected to the needle, where it may be observed and from which a smear can be made for immediate microscopic examination. If the pus contains no organisms I content myself with simple evacuation, to be repeated subsequently if indicated. If organisms are present a metal sleeve is slipped over the needle, which enables one to insert a small piece of rubber tubing, through the capsule without losing it. This simple and safe procedure is particularly applicable to deep abscesses, small abscesses and those in important brain areas. Large superficial abscesses and those in silent areas are, no doubt, more effectively drained by the procedure described by Dr. Cahill or that described by Dr. Adson. Unfortunately, many brain abscesses do not become encapsulated or the intracranial pressure rises to a dangerous point in spite of the usual methods of controlling it, or, in spite of drainage by any of the known methods, spreading, encephalitis or complicating meningitis proves fatal. On the other hand, I can recall two patients who recovered from large abscesses of otitic origin which contained numerous streptococci and had generalized septic meningitis.

DR W. JAMES GARDNER, Cleveland. I was glad to hear Dr. Cahill stress the occurrence of torcular thrombosis. It is a diagnosis that is often overlooked. Many cases of so-called meningismus or otitic hydrocephalus really are cases of thrombosis of the torcular or of the longitudinal sinus. The term meningismus is merely a name coined to camouflage one's ignorance of the true state of affairs. When a spinal puncture is performed in such a case an increased volume of clear spinal fluid escapes. It is therefore customary to say that there exists an increased amount of fluid in the cerebrospinal fluid spaces. This however does not necessarily follow. The large amount of fluid escaping on spinal puncture may be due to increased pressure and not to increased volume. In three cases in my experience in which cerebrospinal fluid was replaced with air for the purpose of encephalography, the total volume of the cerebrospinal fluid was not increased although as much as 60 cc of fluid could be quickly recovered in the course of a simple spinal puncture. The term otitic hydrocephalus as applied to such a case is an actual misnomer. In regard to the use of iodized oil in brain abscess, I have rather hesitated to use nonabsorbable material in an infected field. If a roentgenogram of the abscess cavity is necessary, I prefer to irrigate the cavity with sodium iodide or perhaps introduce a small amount of air. In cases of encapsulated brain abscess in which the localization is in doubt, I feel that encephalography is a perfectly safe procedure. As regards the treatment of abscesses, I am in favor of repeated tapping, especially in long-standing cases rather than of drainage.

DR HARVEY P. CAHILL, Boston. I wish I could have had the good results that Dr. Adson had. In following up the cases I found several in which for many months or longer the patient appeared to be cured when a sudden death took place following so-called uremic coma. I presume that in these cases a complete collapse of the abscess cavity did not occur and that a hemorrhage had probably taken place into the old abscess cavity. I do not believe that packing the cavity would in any way assist the intracranial pressure in obliterating the cavity. If there is a sufficiently extensive fibrosis of the capsular wall to prevent the intracranial pressure from producing a collapse of this wall, packing the interior of the cavity certainly would not assist it. The capsular wall of the otitic brain abscess is thicker and more fibrous than the wall of the metastatic brain abscess. I have also seen cases in which there was not time to wait for the abscess formation to fulfill the demands of perfect localization. I remember one temporoparietal abscess in particular in which the patient became unconscious while the house officer in the outpatient clinic was taking the history. He showed a blood count of 23,000 with a high polymorphonuclear count in the spinal fluid. I performed an emergency subtemporal decompression, drained the abscess with the Mosher wire gauze drain and presented the patient last year at our sectional clinic nine years after the first operation.

FETAL RISKS IN THE FIRST STAGE
OF LABOR FROM UMBILICAL
CORD COMPLICATIONS

CORD DEMONSTRATED BY AMNIOGRAPHY

JOHN P. GARDINER, MD

TOLEDO, OHIO

The emphasis in obstetrics today is centered on the diagnosis of pregnancy,¹ on methods of delivery,² on better obstetric care³ and on morbidity and mortality statistics.⁴ But a discussion of finer obstetric technique and more astute diagnosis for the child is demanded. One such necessary consideration is the effort to explain the death of the fetus during the first stage of labor and the attempt to prevent that death. Complications of the cord, observation and experience have proved to be one cause of death. The diagnosis of a cord complication during the first stage of labor is an achievement in clinical obstetrics.

I have been able to distinguish two groups of cord complicated cases in the first stage of labor. The first group of cases is practically symptomless. The child is fatally asphyxiated from a compression of the cord before the condition is recognized. (This death must not be confused with that due to abruption placentae.) The stopping of the fetal heart is the only evident sign. It usually occurs during the first few pains in the first stage of labor but may occur from a few hours to several days before labor definitely sets in. The following case reports will illustrate the hopelessness of being able to deliver a live child under these conditions.

CORD COMPLICATION CASES IN WHICH THERE ARE
NO SYMPTOMS

CASE 1—Painful contractions began at 2:20 p.m. the second pain was at 3 o'clock, light painful contractions continued every twelve to fifteen minutes, producing a heaviness in the lumbar region. At 5:30 it was impossible to hear the fetal heart beat. The head was deep in the superior strait. There were active fetal movements as the patient left for the hospital but none after her arrival. The family was informed that the fetus was probably dead, owing, no doubt to a cord complication the compression of the cord disturbing the circulation long enough to cause fetal death. Labor was allowed to progress and at 11:30, after the birth of the head the cord was found to be coiled about the neck in a reverse coil so that the taut, umbilical portion crossed over the placental portion at the left sternoclavicular joint where the cord was compressed by the chin. Postmortem examination revealed no other cause of death.

CASE 2—The patient was allowed to be up and about her room. She was noticing some heaviness only in the upper part of the thighs but no definite painful uterine contractions. When

I saw her about an hour after admission, no fetal heart beat was audible. The fetus had not been active since the afternoon of the day before. The fetal head was fixed in the superior strait. I suggested to the family that the cord was probably compressed under the chin and thus the anterior flexion of the fetal head obstructed the cord circulation and fatally asphyxiated the child. At birth, fourteen hours later, the cord, taut from the umbilicus, was found in a reverse coil about the neck with the crossing under the chin, the place of compression. Autopsy did not show any other cause of death.

CASE 3—The patient had been having preliminary labor pains at recurring intervals for the previous week. In the office, the day before admission, the fetal heart, left below, was of good tone and the rate was 130. On rectal examination, the head in the pelvis was engaging in the ischial-ramic⁵ diameter, the lower uterine segment was obliterated, the cervix was high posterior 1 cm long, hydrated and patulous 1 cm. The activity of the child awakened the patient about 4 a.m. the next day. At 6 o'clock she was admitted, as the uterine contractions were more uncomfortable recurring every three to five minutes. At 6:30 the fetal heart beat was not audible, in direct contrast to the good heart beat of the day before. It was intimated that the cord had become compressed with probably a reverse coiling or with a loop of the cord. At birth thirteen hours later, a reverse coiling about the neck was found on the 7½ pound (3400 Gm) child with the placental portion of the cord over that of the fetal portion, which was taut from the umbilical end.

The following case is an example of fatal compression of the cord by the fetal extremities.

CASE 4—Mrs. C., aged 33, an octipara, stated that she was one and one-half months overdue. Her weight was 244 pounds (110.7 kg). The abdomen was large but not pendulous as there was no diastasis recti abdominis. The fetus was large and the head was well engaged in the superior strait. Back to the left, fetal heart tones were audible and the rate was 124 per minute. The birth canal was relaxed, owing to a second degree tearing and an old bilateral laceration of the cervix complete to the left and half way to the right. The abdomen contained about 5 inches of fat. The child and the uterus occupied practically the whole abdominal cavity, as there was little liquor amni. The patient refused, not being yet in labor, all advice for relief. The nurse reported fifteen days later that the fetal heart was audible, below to the left, and that the rate was 126 per minute, the patient said that if she could be repaired she would come in in a few days as she was a little worried. Examination on admission, sixty days overdue, revealed little added information except that now there was no fetal heart sound. On questioning the patient it was found that at 11:30 the night before admission the child moved very freely but thereafter no movement was noticed. It was then assumed that the excessive movements were agonial and that death was caused by a compression of the cord which stopped the circulation. Labor was induced with solution of pituitary and a 12¼ pound (5783 Gm) dead male child was delivered after a tedious birth. The cord was found to be coiled about the right thigh and again behind the right knee, where it was compressed by the left knee, when it coiled about the left calf and again about the right ankle. These coils used up the entire length of the cord which was 50 cm. The mother was repaired and recovered uneventfully.

It is to be pointed out that there were in these cases until the death of the fetus, no previous indications of a cord complication. In order to understand the gravity of cord complications it is to be remembered that reverse coils on slipping down over the body of the child, form true knots in the cord, while ordinary coils of the cord on slipping down, just add another twist to the torsion of the cord. For the compression to take place it is only necessary that the reverse crossing of the cord be securely caught for example

between the chin and the chest as when pressure is exerted by the fundus on the buttocks, forcing the fetal chest against the chin which remains stationary, owing to the resistance the fetal head encounters when driven against the resistant undilated lower uterine segment. If this position is retained sufficiently long, death ensues. It is the 100 per cent mortality rate in such cases that gives grave concern. So unrecognized are the symptomless coils in this first group of cases and so sudden is the fetal death that, at the present time, it is impossible to expect to save the life of the child by any method of delivery, yet it is not inconceivable to believe that if it was recognized that the fetal cord was being compressed and if delivery was immediately carried out, the child might be saved.

CORD COMPLICATION CASES IN WHICH THERE ARE SYMPTOMS

The second group of cord complicated cases in the first stage of labor includes those which do show symptoms. The prognosis for this group is more hopeful, since there is a chance for the obstetrician to diagnose the cord complication and to save the life of the child. There are three cardinal symptoms that suggest a cord complication: delay in the progress of labor, disturbance in the fetal heart rate and a malposition of the fetus. (Pain at the placental site a definite symptom due to traction, occurs later in the first stage and in the second stage of labor.) There may be, in a single case, all or only one of these symptoms.

Labor is a progressive process and does not normally admit of delay. Any delay in labor is an important symptom and must never be ignored. Delay may mean a cord complication, a dry labor (oligohydramnios), a disproportion (bony or soft parts) or thick unruptured membranes, the importance to the child being in the order given. The latter three symptoms—oligohydramnios, disproportion and thick membranes—can be so easily recognized that they allow a diagnosis of a cord complication by the process of elimination, at least a tentative diagnosis can be made that the cord is so coiled about the parts of the fetus as to interfere with the free progress of labor. This symptom has great possibilities for study.

Variation in the fetal heart rate is the most urgent symptom in the process of delivery. I have found it to be frequently associated with a cord complication. To understand fully the mechanism of the fetal cardiac variation caused by a cord complication it is necessary to recognize the importance of muscle tone in involuntary muscles (of which the uterus is the largest). During labor the action of the uterine involuntary muscle is exaggerated. It has been pointed out that the uterus is contracting and relaxing during the entire period of pregnancy, indeed to a lesser degree at all other times as well. The contractions and relaxations can be observed by the sense of touch and even in some cases by the sense of sight before the onset of labor, in the alternate hardness and softness of the uterine muscle. While these contractions are harmless in themselves, it sometimes happens that a portion of the cord is imprisoned and compressed until there is a definite oxygen want when the fetal movements are increased, stimulated by the struggle for oxygen, and the cord is usually released and the circulation

restored. But if the compression is not relieved as fortunately happens rarely (it is in cases of extreme torsion of the cord at the umbilicus that this fatal accident occurs earlier in pregnancy than do the difficulties discussed in this paper), and if the uterus contracts synchronously, increasing the compression long enough and keeping the child from recovering consciousness sufficiently to extract the cord from the compression (a fatality which occurred in the first four cases reported) the child will die from asphyxia due to failure of cord circulation.

This compression does not however take place as often as one might think for the pulsating vessels tend to assist the moist cord to squeeze out of the trap. Another fortunate provision of nature is that the vessels of the cord are longer than the cord itself. Unless the cord is put on excessive tension the vessels are still not stretched to compression and the blood flow of the cord is not greatly diminished. As is well known, a knot in the cord rarely causes trouble for it recoils on itself because of the presence of the jelly of Wharton. But when there is a coil about the neck the surface of which is more resistant than the surface of the cord, particularly if there is little vernix caseosa and little jelly of Wharton it slips only under increased traction, with increased traction there is a greater chance of compression. The fetal heart rate is a good criterion of the well being of the fetus. The mother's statement that she has recently felt life is not always dependable but feeling the movements while auscultating the abdomen is a sure sign that the fetus is still alive. In the examination of the fetal heart (often a difficult task) it is of great assistance to take simultaneously the maternal pulse. The actual value of the interpretation of the fetal heart rate is not sufficiently appreciated in defining the gravity of active cord complication.

A malposition is the third symptom of cord complication which may draw attention to the fact that the fetus is in danger. If there is no disproportion of the soft or bony parts, tumors fetal or maternal, or fetal monstrosities, a cord complication should be definitely suspected in malpositions. Finding the fetus either fixed or limited in motion in an abnormal position is a probable indication of cord complication. The cord may admit of some movement and an attempt may be made at conversion into a head position, the attempt will proceed just so far but when the force is removed the part will gradually return to its original position. (It is to be remembered that when there is a small or lessened amount of liquor amni the irritability of the uterus may be so active as to cause it to contract down on the fetus, thus permitting little correction in the position.) But, when each attempt at correction is accompanied by a disturbance of the fetal heart rate, a cord complication must be inferred.

TREATMENT

The choice of treatment to be followed in cord complicated cases is dependent on the diagnostic observations. Delay in the progress of labor (it cannot be said that the ideal treatment for delayed labor is to be satisfied with complacently giving a sedative and dismissing the case for the time being), variation in the fetal heart rate and persistent malposition of the child, the amount of liquor amni, the degree of hydration of the cervix and the dilatability of the perineum will influence the

choice of the method of delivery. It is only rarely that a section must be performed in any cord complication but when the indications point to a section it is to be performed and in time to save the child. My first case in which a diagnosis of cord complication was made but the courage of my convictions was not strong enough to carry out my purpose of doing a cesarean section until it was too late is still vividly in my mind.

CASE 5—Mrs. F., aged 20, a primipara, had recurring painful uterine contractions for five hours before admittance. The pelvic measurements showed a roomy pelvis. The cervix was not dilated and was 15 cm long. The position of the fetus was transverse, with the head to the right above the anterior superior iliac spine, and the buttocks were to the left. There was an average amount of liquor amni. The fetal heart at the umbilicus was of good quality and its rate was 135. The membranes were intact. The position could not be changed by reasonable attempts and it persisted in there with slowing of the fetal heart rate. A cord complication was diagnosed. After three hours of increasingly strong uterine contractions there was no change (certainly a delay in the progress) and the fetal heart rate was 130. It was decided that if there was no change in another three hours a cesarean section would be performed and the order was given to prepare for it. The family was acquainted with the decision and accepted the suggested method of treatment. One hour later even though an examination had been made every five minutes the nurse reported that the fetal heart beat was inaudible. The labor was now allowed to proceed and ten hours later a dead female child was born. The taut cord was deeply coiled about the neck and ran around the neck again posteriorly where it coiled about the opposite arm then to the placental attachment. A tentative effort was made in this case to perform a section to save the child.

The case well illustrates two points: the one that if there is any delay in the continuous progress of labor, it ceases to be one of average labor and becomes one in which the attitude of watchful waiting changes to that of active intervention which may mean that an immediate section is necessary to save the child. The other point is that after fetal death the need for a rapid delivery may be immediately over. It is well known that the dead fetus causes less trouble in delivery than a live child. The blood pressure and the general tone being reduced, the child becomes smaller and more compressible. The following case reports demonstrate the significance of the symptoms of fetal heart disturbance and the urgent necessity of immediate action in the emergency.

CASE 6—A woman, after a diagnosis of a cord complication was made, was prepared for a tentative section. Labor was allowed to continue, however, for a time. Because of the failing fetal heart a cesarean section was performed and fortunately a living child was secured.

CASE 7—Mrs. R., a primipara who was at term entered labor with the fetus in a transverse position, maintained in spite of reasonable attempts at conversion into a head position. The pelvis was roomy, there was a moderate amount of liquor amni and there were no abnormalities. While pressure was exerted on the head the fetal heart beat decreased in rate. At one time it went as low as 110 per minute, as soon as the pressure was removed the rate went up as high as 160 later returning to 140. A cord complication was suggested. The patient was prepared for a tentative section but was permitted to continue in labor. Later the fetal heart began to fail there was no cervical dilatation, the membranes were intact and the position of the fetus had not changed (delay in labor). A section was done immediately. The cord with a coil about the neck was cut from the placental insertion; the fetal portion ran from the umbilicus under the perineum up the back to the neck, there completing the coil. The length of the cord

was 55 cm. The deeply asphyxiated child was resuscitated with difficulty. The recovery of the mother and the child was uneventful.

Though case 7 was observed as closely as possible, it is seen that the section was delayed almost too long for the safety of the child.

The following case report illustrates a cord complication retaining the fetus in a breech position, which complication was diagnosed and demonstrated at operation.

CASE 8—Mrs. B., aged 21, a primipara was in good health and weighed 200 pounds (90.7 Kg). Pelvic measurements showed a moderately roomy pelvis. There was a moderate amount of liquor amni. The examination at term still revealed a breech position with the buttocks at the superior strait. The fetal head was in the left hypochondrium, and the back was to the right. The fetal heart was heard 2 cm above the umbilicus. Several efforts had been made to convert the head into a vertex presentation, but it was still impossible under reasonable manipulation to bring the head to the transverse position. On cessation of the effort, the head quickly resumed its original position. The fetal heart was 130 but slowed down to 110 during the trial of conversion. I was of the opinion that the child was so entangled in the cord that the movements were greatly limited. The family was informed that the child could possibly be born but I felt that the chances of a live child were about 50 per cent through the birth canal and probably 100 per cent by cesarean section. The section was chosen. As the case was perfectly clean, labor not having started, the high operation was done so that the cord difficulty could readily be of access. When the membranes were ruptured the cord was seen about the neck with no slackness. The head was delivered; the cord ran from the neck to the left axilla and coiled high about the right arm to the placenta. The true cord intertangling with further delivery was cut and the child delivered. The cord was 60 cm long.

The condition was demonstrated to those about the operating table. In this case there was more than usual risk in allowing the birth to take place by the natural birth route.

It is not good or reasonable obstetric practice to advocate a section in all breech cases that present a cord complication, yet there is more than the usual possibility of the cord being compressed in such breech deliveries than when there are no entanglements about the various fetal parts. The obstetrician should not be too radical⁸ or too conservative,⁹ but ought to stand on the middle path. When the cases just recorded presented a moderate amount of liquor amni, a delay in the progress of labor, no demonstrable abnormalities to prevent the correcting of the malposition, and a slowing of the fetal heart rate on the attempts at turning, it was concluded that the fetuses were dangerously entangled in the umbilical cord and that their chances of surviving the natural birth route were markedly decreased.

It is with cumulative enthusiasm that a new help in obstetrics is gradually being developed. The impossibility of being able to see its difficulties has been one great handicap in the practice of obstetrics. It is now becoming possible to visualize some of the problems that confront the obstetrician. The introduction of roentgenography into the field of obstetrics has great possibilities and without a doubt, will revolutionize both the teaching and the practice of the art. Though the roentgenogram has its limitations yet once the value of visualization is realized the obstetrician will be able to demonstrate his skill in delivery.

⁸ Williams, J. W. The Abuse of Cesarean Section. Surg., Gynec. & Obst. 25: 194-201 (Aug.) 1917.

⁹ Reynolds. Circumstances Which Render the Elective Section Justifiable in the Interest of the Child Alone. Am. Med. 2: 480, 1901.

"Amniography" ¹⁰ (and I accept the name given by Mences) consists of injecting from 10 to 15 cc of some opaque solution skiodan or strontium iodide directly into the amniotic sac and after one-half hour (time for distribution) a roentgenogram is taken. In the roentgenogram the cord as well as the position of the placenta can be outlined and at times the sex can be made out. To be able to trace the cord in a cord-complicated case encourages one to proceed with more confidence in one's outlined method of delivery. The roentgenogram is a permanent record which permits checking back on the technique of delivery in a way not before possible. I have used it now in a series of eight cord-complicated cases. The value of amniography in a difficult case is brought out in the following report.

CASE 9—Mrs. A., a primipara, was at term with the fetus in an inconvertible breech position. Attempts at turning succeeded in moving the head about 45 degrees; it would return to the original position immediately and if the effort was persisted in it caused a disturbance in the fetal heart rate. There was little liquor amnii. A serious cord complication was suspected and consent to a section was secured should it be necessary. The patient was permitted to fall into labor. "Amniography" was used. The roentgenogram showed the cord running up around the back. The placenta was located and the shadow of the scrotum was made out. Labor progressed, the lower uterine segment was obliterated and the cervix was dilated 0.5 cm. There was as yet no disturbance of the fetal heart rate. Since the cervix was well hydrated and the perineum easily dilatable the fetus descended and retracted between the uterine contractions, the fetal heart rate appeared undisturbed and the roentgenogram showed no entanglement about the neck or extremities; it was felt that in spite of the traction of the cord the child could be born by breech presentation. The attempt succeeded. The child was breathing before the birth of the aftercoming head as air was permitted to reach the mouth by way of the vagina. The cord was short 42 cm and had been squeezed up off the body of the child and no doubt the rotation of the fetus allowed the slipping up of the cord. At birth there was no visible demonstration of a cord complication except the shortness of the cord. I have learned that this negative evidence is untrustworthy. In this particular case the roentgenogram showed the cord running about the body.

The visualization of the umbilical cord by means of 'amniography' gave a feeling of confidence not before experienced. It is reassuring when the postoperative diagnosis coincides with the preoperative. The more one becomes acquainted with the symptoms of cord coiled cases the more accurately will preoperative and postoperative diagnoses agree and greater aid will be rendered to both the child and the mother.

CONCLUSIONS

Cord complications too frequently during the first stage of labor cause fatal asphyxiation of the child for which no blame can possibly be laid to the conduct of labor.

The symptoms of cord complications are delay in the progress of labor, disturbance in the fetal heart rate and retained malposition of the child.

Not every cord complication means a cesarean section. But when the definite need for it has been demonstrated the section must be done in time.

'Amniography' has a place in diagnosis as it is an aid in demonstrating a cord complication. This verification gives courage to pursue the outlined treatment.

ABSTRACT OF DISCUSSION

DR WILLIAM J. DICKMANN, Chicago. I have always insisted that the fetal heart tones must be counted every twenty minutes during the first stage of labor and every five minutes during the second stage and that the rate must be recorded. However, textbooks on obstetrics contain little or nothing about fetal risks or death in the first stage of labor. To determine its importance I reviewed 1003 fetal autopsy records which had been collected by Dr. Adair. There were 136 stillbirths or 13.6 per cent of 2000 Gm or over in which the cause of death was either a cord complication or unexplained. In four cases the cord was prolapsed and in nine the cord was coiled around the neck from one to four times. In one case it was round the thighs. Thus 1 per cent of these stillbirths was caused by a diagnosed cord complication. The remaining 125 or 12.4 per cent may have been caused by similar conditions. At least nothing was found at autopsy other than the symptoms and signs of suffocation. The treatment of intrapartum cord compression is of the utmost importance and is as follows: (1) the use of posture—knee-chest, Trendelenburg or the turning of the patient on one side or the other, and (2) a vaginal examination to determine whether or not the cord is prolapsed, and also the condition of the cervix. The fetal mortality of from 60 to 90 per cent in open and concealed prolapses of the cord demonstrates conclusively that radical intervention is unwarranted for the sake of the baby and maternal mortality statistics indicate its dangers to the mother. In the first stage in addition to the use of posture in intra-ovular bag may be of value. In the second stage with a completely dilated cervix and the head engaged an experienced man will deliver with forceps or, with an unengaged head by version. It is surprising how many cases the fetal heart tones are slow and occasionally irregular, yet the baby is born alive after a spontaneous labor. Dr. Gardiner reports two cesarean sections performed because of slow fetal heart tones in the first stage of labor. For slow or irregular heart tones in the first stage of labor I have not to date performed cesarean sections. I made Dührsen's incisions or dilated the cervix manually although I can recall a number of cases in which I was importuned by the house staff to do something, when a forceps delivery or version could not be done by them with safety. I believe that we as teachers should do no operative procedure that we cannot entrust to a trained resident much less an intern.

DR F. I. KING, New Orleans. I wish to add to what Dr. Dickmann has said regarding the auscultation of the fetal heart tones. I have found that there are a few signs that are of great value in this connection. I notice that immediately after a contraction the heart tone normally is irregular. On the other hand if the baby is in grave danger from prolongation and undue pressure particularly in the second stage of labor there will be a slowing and irregularity of the fetal heart tones throughout the entire period between the pains. If there is a cord complication such as the cord round the neck there will be a slowing and irregularity of the fetal heart tone for a period longer than is normal but not for the entire period of the pain. That to me has been of great value in diagnosing cord complications particularly in cases in which the cord is found to be round the neck. To my mind it has meant that obstetricians should not be in such a great hurry as they should be when the heart tone is irregular and slow for the entire period between the pains. I think that would be of value in the class of cases under discussion.

DR W. PARKS PHILLIPS, La Grange, Ga. In a case of fatal asphyxia due to a complete knot in the umbilical cord some 8 inches from its attachment to the baby this condition was not detected during labor. At delivery I had a dead infant and on inspection of the cord I found a complete knot, which was drawn sufficiently tight to asphyxiate the baby.

DR JOHN P. GARDINER, Toledo, Ohio. The position I take in regard to the symptomatology of cord complications has been forced on me by observation and experience. The three symptoms of a cord complication which I have worked out are delay in labor, disturbance of fetal heart rate, and malposition. One can be very suspicious of a cord complication when one finds these three symptoms. It is difficult as yet to explain fetal death. Very little that is pathologic is shown in death due to asphyxia; this fact in itself gives great leeway for varied opinions as to the

Mences, T. O., Miller, J. D., and Holly, I. F., Am. J. Roentgenol. 24:363 (Oct.) 1930. Ehrhardt, K., Zentralbl. f. Gynäk. 56:947 (April 2) 1932. Staveley, Dulcine, Brit. M. J. 1:937 (May 21) 1932. Kerr, J. M. M., and Mackay, W. C., Edinburgh M. J. 40:2132 (March) 1933.

etiology. The accumulated evidence is that many of the fetal deaths which are unaccountable are due to asphyxia. It is reasonable to assume that a cord (usually 55 cm long or longer) mobile and subject to frequent changes of pressure especially in oligohydramnios, may be compressed causing fetal death. I sympathize with the doctor who spoke of being unable to find the fetal heart beat. Sometimes the difficulty is insurmountable. I stated that, under certain conditions, one cannot be sure that the child is alive unless one feels the fetal movements. One cannot accept the statement of the woman that she feels the fetal movements because she may say she feels them when a fetus is not even present. When one has gotten continuously a distinct fetal heart beat, no matter by what method, it is very difficult to remove the psychologic effect in one's mind and the physiologic effect on one's ear to distinguish at times whether or not the heart is still beating. But when a heart has been beating strongly and regularly and then suddenly ceases, there is grave concern and the simplest method of explaining it is that there is a cord compression. I did not read the case histories included in the paper—three definite histories in which the cord was pinched in a reverse coil between the neck and the chest and was so found at birth, with no traction on the placental side of the cord. The traction was on the fetal side of the cord where the flexion held the cord as it was crossed at the neck until the fetus died. I feel that these cord complicated cases should be more carefully observed, there will then be more definite information in the literature. Matthew Duncan was deeply interested in the study of cord complications, but very few others have followed in his lead.

THE ETIOLOGY AND TREATMENT OF ANEMIA IN PREGNANCY

MAURICE B. STRAUSS, MD

BOSTON

Numerous workers¹ have established the existence of a distinct lowering of the hemoglobin concentration in the blood of normal pregnant women. The nature of this "physiologic anemia" and of recovery therefrom has remained confused because seldom have intensive studies been made of the blood of normal women month by month from early pregnancy through and after the puerperium. Such studies² show a steady decline in both hemoglobin and red blood cells from early in pregnancy until the end of the second trimester, after which either no further change or a slight rise occurs. However, observations indicate that within ten days of parturition normal women who have had no significant defects of diet or gastric secretion during pregnancy show an abrupt rise of both hemoglobin and red blood cells to essentially the levels held at the beginning of pregnancy. Correlation of these data with known changes of blood volume in pregnancy indicate that this "physiologic anemia" of pregnancy is not anemia at all in the usual sense, but merely hydremia. Furthermore once the blood volume readjustments of the puerperium are over, no further change of significance occurs during three months post partum.

In contrast to these manifestations it was observed³ that the hemoglobin of a group of pregnant women with complete posthistamine gastric anacidity continued to decline in the last trimester of pregnancy and, after blood volume readjustments were complete, remained 18 per cent below the initial level.

In another group of women who had gastric hypochlorhydria during pregnancy, the same state of affairs was observed with, however, a net lowering of the hemoglobin of only 9 per cent. A fourth group of pregnant women had gastric hypochlorhydria and partook of diets low in iron during pregnancy, the average hemoglobin was 14 per cent lower after pregnancy than at the onset.

It is obvious that pregnancy may be a coincidence during the course of any number of diseases which in themselves cause anemia, such as leukemia, infections and cancer. Furthermore, the gravid state may be responsible for hemorrhage, nephritic and eclamptic toxemias and puerperal sepsis, all of which may produce anemia. Disregarding these anemias of known etiology, there remains a large group of patients who develop a severe anemia during pregnancy which has no obvious cause. Two kinds of such anemia are encountered—one hypochromic in character, the other macrocytic (pernicious) in type. The former has all the characteristics of what has been known in the past as chlorotic anemia or simple secondary anemia and for which more recently idiopathic hypochromic anemia has been the term of choice, since it expresses the fact that the reduction in hemoglobin greatly exceeds that of the red blood cells.

Generally, idiopathic hypochromic anemia occurs in persons who have gastric secretory defects and poor diets. When women suffering from these defects become pregnant, not only may a preexisting anemia be much enhanced but severe anemia may develop during the pregnancy. In the hypochromic anemia of pregnancy there is seldom significant alteration in leukocytes or blood platelets, but stained films show small pale erythrocytes. The chief presenting clinical symptoms are pallor, lack of a sense of well being and excessive fatigability. In the very severe cases edema, dyspnea, prostration and syncope may be observed. Rarely is enlargement of the spleen detected.

Thirty patients with this type of anemia in pregnancy were studied,³ all of whom had severe anemia, with less than 45 per cent hemoglobin (Sahli). Rigorous examination failed to reveal concomitant disease or loss of blood. Since this type of anemia resembled the common hypochromic anemia associated with poor diet and gastric secretory defects, these two factors were investigated. Seventeen of the thirty patients had complete posthistamine gastric anacidity, even when examined after parturition. Ten patients had little or no free hydrochloric acid in the gastric secretion after the usual alcohol test meal, and diminished amounts after histamine stimulation. Two patients only had normal gastric acidity post partum.

With but one exception all the patients who did not have complete anacidity had partaken of diets poor in iron not only throughout pregnancy but often over a period of years. Eight of the seventeen patients with complete absence of gastric free hydrochloric acid had partaken of good if not optimal, diets throughout pregnancy, while the remainder had not had an adequate intake of iron-containing foods. It was thus apparent that either gastric secretory defects or diets deficient in iron-containing foods, or both these factors, were present in all thirty of the patients with hypochromic anemia developing in pregnancy. The relationship of gastric acidity to the absorption or utilization of iron has been discussed elsewhere.⁴

In addition to these disturbances it is to be remembered that all these women had what is comparable to loss of blood, since all their infants were born with normal amounts of hemoglobin, no matter how anemic the mothers. The building material for the fetal hemoglobin was of necessity derived from the maternal organism and represented that much loss to the mother.

Treatment of these patients, after control periods without therapy was uniform. Six grams of iron and ammonium citrate was administered daily. Without exception, and irrespective of whether treatment was instituted during or after pregnancy, prompt regeneration of hemoglobin and red blood cells occurred with the restoration of the patient to complete health. Furthermore, the infants born to women severely anemic in pregnancy uniformly develop anemia during the first year of life. If the mothers are adequately treated during pregnancy, this does not occur.

Less patients suffering from the macrocytic (pernicious) anemia of pregnancy were observed.¹¹ These patients usually were more seriously ill than those with hypochromic anemia. They had red blood cell counts of under 2.5 million per cubic millimeter and, in addition to the symptoms of anemia mentioned under the hypochromic type, marked nausea and vomiting occurred in five and diarrhea in two patients. Fever, without demonstrable infection abating when intravenous therapy was employed was observed in nine patients. Soreness of the tongue was present in four patients and splenomegaly in two. Mild combined sclerosis of the spinal cord developed once. All but one patient had had during pregnancy and frequently prior to it, a distinctly limited intake of animal protein food.

In these women the number of erythrocytes was more markedly diminished than the amount of hemoglobin, resulting in a color index above 1. The red blood cell counts varied from 1.05 to 2.5 million per cubic millimeter and the hemoglobin from 20 to 50 per cent (Sahli). In stained films the red cells showed moderate variation in size and shape with oval macrocytes, microcytes and an occasional tailed form. Rarely megaloblasts were observed. Mean corpuscular volume determinations showed a somewhat increased cell size (from 105 to 130 cubic microns), on the average not so marked as in Addisonian pernicious anemia. The concentration of hemoglobin in the red blood cells was, however, slightly reduced. The leukocytes and blood platelets were either normal or slightly decreased. A relative increase of lymphocytes accompanied the leukopenia in most cases. The serum color was either normal or slightly more yellow than normal. In five of these patients achlorhydria occurred, in four hypochlorhydria and in one normal acidity of the gastric contents after histamine injection. One patient with achlorhydria, when reexamined two years later, showed normal acidity.

It was therefore apparent that these patients with macrocytic anemia of pregnancy, like those with hypochromic anemia had both defects of gastric secretion and deficient diets, the latter being chiefly lacking in animal protein.

These patients can be relieved of their anemia with liver or potent liver extract administered by mouth or by injection, just as in Addisonian pernicious anemia. However, once completely well relapse does not ordinarily occur as it does in the Addisonian type, unless pregnancy again occurs. Practically all these patients had in addition to the deficiency of the true

pernicious anemia type, referred to later, an added deficiency correctible by iron therapy. The loss of hemoglobin to the fetus may well explain this. Experiments¹² pursued over a number of years have shown that Addisonian pernicious anemia is due to a failure of a reaction to occur between a stomach factor present in normal gastric juice and a diet factor associated with vitamin B. It has been shown that a lack of the stomach factor alone or a lack of the diet factor alone may result in a failure of this reaction essential for hematopoiesis and in rare cases it is believed that a failure of absorption may produce the same effect, even though stomach and diet factors are normal. Accordingly experiments were undertaken to determine whether the same mechanisms of deficiency were responsible for the macrocytic anemia of pregnancy.

It was found that these patients generally had a partial lack of the stomach factor, since the administration of 200 Gm of beefsteak or 16 Gm of autolyzed yeast (both rich sources of vitamin B) produced some improvement as measured by reticulocyte responses and since greater effects were obtained when, in addition 150 cc of normal human gastric juice was administered with the beefsteak or yeast. In one patient experiments showed no stomach factor whatever present during the last ten days of pregnancy, with a moderate amount reappearing within a week of parturition. This patient later showed a partial loss of this factor in the seventh month of a subsequent pregnancy.

These observations then indicate that analogous mechanisms are involved in the production of the macrocytic (pernicious) anemia of pregnancy and Addisonian pernicious anemia.

Other observations¹³ indicate that disturbances of gastric secretion occur to a greater or lesser extent in more than half of pregnant women. In order to prevent the development of anemia in pregnancy it is therefore essential that a diet adequate in iron and in protein be consumed. It may well be advisable in practice to supplement the diet with iron, as is commonly done with calcium.

If the gastric secretory defects are so marked that an adequate diet alone does not suffice to prevent anemia iron in sufficiently large doses such as 6 Gm of iron and ammonium citrate daily, should be prescribed for the hypochromic type of anemia and potent liver extract derived from 300 to 600 Gm of liver daily for the pernicious type of anemia. If vomiting prevents oral administration from 2 to 5 cc of a potent solution of liver extract for intramuscular use such as No. 343 N. N. R., may be given daily. In very severe cases, and especially if infection supervenes, transfusion of blood in addition to the measures described may be necessary to save the life of the patient until the bone marrow commences to pour out new erythrocytes. Otherwise blood transfusion is generally unnecessary and may sometimes be dangerous.

CONCLUSIONS

- 1 The "physiologic anemia" of pregnancy is only the effect of hydiemia.
- 2 The hypochromic anemia of pregnancy is due either to a direct dietary deficiency or to a deficiency conditioned by gastric anacidity, hypochloridity or aso-

6 Castle W. B. Am. J. M. Sc. 178:748 (Dec.) 1929. Castle W. B. and Townsend W. C. *ibid.* 178:764 (Dec.) 1929. Castle W. B. Townsend W. C. and Heath, C. W. *ibid.* 180:305 (Sept.) 1930. Castle W. B. ciated defects in the presence of the fetal demand for blood-building materials. It may be completely relieved either during or after pregnancy by the administration of iron in suitable (usually large) doses.

3 The macrocytic anemia of pregnancy is generally due to a temporary lack in the gastric juice of a specific intrinsic factor which has been shown to be absent from the gastric juice of patients with Addisonian pernicious anemia in relapse. The ultimate complete return of this factor after delivery is hypothesized. In other cases the lack of the extrinsic factor (associated with vitamin B) from the diet may produce similar effects. The macrocytic anemia of pregnancy ordinarily may be completely relieved with liver extract, although iron is frequently required in addition.

4 The similarity of the etiologic mechanism involved in the hypochromic anemia of pregnancy and idiopathic hypochromic anemia in the absence of pregnancy, and in the macrocytic anemia of pregnancy and Addisonian pernicious anemia, is pointed out.

5 The development of anemia in pregnancy may best be prevented by supplying the pregnant woman with an adequate intake of blood-building materials.

LEG ULCERS DUE TO THYROID DYSFUNCTION

MILTON H. COHEN, M.D.

YORK, PA.

The conception of the skin as an organ of the body intimately connected with the other organs and not merely a protective covering is too obvious to need any repetition or emphasis. However, in the studies made of skin diseases, attention has been directed chiefly toward the skin itself and the effect of internal influences has been generally overlooked. Every textbook under the caption of etiology will make a casual reference to metabolic disturbances, influences of the central nervous system, and the importance of the endocrine system, but, from a practical standpoint, little has been done to utilize these systemic changes in therapy. The treatment of cutaneous disorders is still essentially a local problem and very few conditions are relieved by specific internal therapy. Andrews¹ states that in the obscure field of endocrinology, one finds expressions of glandular dysfunction of the skin more than in any other organ and illustrates this statement by the examples of myxedema, chloasma and the pigmentation of Addison's disease, but, in view of the great incidence of endocrine disturbances, it is surprising how few cases of skin changes have been reported as due to dysfunction of the hormones. Richter² quotes Virchow as pointing out that the stimulative properties of the hormones are nutritive, functional and formative. They work independently in part and in part through the nervous system. They regulate metabolism, govern growth and serve as a stimulus to the preservation of the organic structure. The endocrine glands play a greater role in view of these multitudinous functions in the etiology of cutaneous disorders than they are given credit for. For many years glandular products have been used in dermatologic therapy for a great variety of cutaneous ailments but the amount of thera-

peutic success has been small and controversial reports have been many.

Of late the relationship between disturbances of the thyroid gland and peculiar skin changes in the lower extremities has been arousing interest. An odd eruption of the legs following thyroidectomies has been observed by various dermatologists all over the world. Hektoen³ gives the first reference in the literature of a bilateral, mucilaginous, circumscribed infiltrate of the legs associated with exophthalmic goiter. Dubreuilh⁴ first described a myxedematous nodular infiltration of the skin unassociated with exophthalmic goiter. O'Leary⁵ gave the case histories of eight patients observed in the Mayo Clinic showing myxedematous plaques in the legs associated with thyroid disturbances. He termed this condition "circumscribed myxedema." Pillsbury and Stokes⁶ reported one case in great detail and exhaustively reviewed the literature. Netherton⁷ presented a case before the Cleveland Dermatological Society and Wright,⁸ likewise, before the Atlantic Dermatological Conference. Von Lewtschenkow⁹ first showed the myxedematous nature of this condition and Dossekker¹⁰ termed the ailment an atypical tuberous myxedema. Slonimskaya and Glauberson¹¹ consider the skin changes found in thyroid insufficiency due to a cutaneous dysarthrosis, a part of a general dysarthrosis symptom complex. They report three cases of atypical circumscribed myxedema and speak of twenty-eight more cases recorded in the Russian literature. Kilbourne¹² cites a most unusual case in which an enormous ulcer of seventeen years' duration on the lower part of the right leg healed completely in ten weeks after the daily ingestion of 15 grains (1 Gm.) of thyroid extract. With the exception of Kilbourne's case, I have not been able to find reported in the literature another example of leg ulcers definitely shown to be due to thyroid dysfunction. In view of the comparative frequency of thyroid disturbances and the great number of thyroidectomies done every year, it is surprising that more such cases are not on record. Because of the rarity of this condition, the following case is reported as an example of leg ulcers produced by dysfunction of the thyroid gland.

REPORT OF CASE

History—A white woman aged 39, a native of Pennsylvania, had done housework all her life. In February, 1925, she noticed a rash on her legs which itched considerably. The eruption consisted of red round marks that were slightly raised and extended from her ankles to above her knees. In a few weeks small ulcers appeared varying in size from a pea to 24 mm. in diameter. Gradually the ulcers spread, coalesced and became deeper. These extensive ulcerations remained on her legs despite a great variety of therapeutic procedures until her admission into the York Hospital in October, 1931. In August, 1925, she first noted that her neck was increasing in size and she was informed by her physician that she had a goiter. The swelling became larger and persisted until her

admission to the hospital. She suffered from severe headaches almost migrainous in character, and had noted a marked thinning and coarsening of her hair. Her menses began at 13 and had always been regular until the last six years, when they became scanty and infrequent, often missing three or four months. She was the mother of eight children, living and well, and had one miscarriage before the birth of her oldest child. Her past medical history was of no consequence. Her mother died of tuberculosis, but she had a father, five brothers and four sisters, living and well and free from any acid-fast infection.

Examination—The irises reacted normally to light and in accommodation. Her eyes showed no exophthalmos or the other characteristic signs of exophthalmic goiter. The thyroid gland was enlarged symmetrically with a doughy consistency. A bruit was present over the gland. Her skin was dry and shiny, giving an almost translucent appearance. Her hair was sparse and coarse, with a moderate alopecia. On both lower extremities large ulcers

Fig 1—Left leg three days after admission to the York Hospital in October 1931

were present above and below the active lesions. No varicose veins were observed. Dorsalis pedis pulsations were present in both legs. The heart and lungs were normal. She appeared rather sluggish and slept a good deal during the day.

The urine was normal except for a faint trace of albumin. A blood count showed 3 500 000 red cells, 75 per cent hemoglobin, 8 500 white cells, and a normal differential. The blood sugar was 92 mg per hundred cubic centimeters. Two Wassermann tests of the blood were negative and the spinal fluid showed a negative Wassermann reaction in all dilutions and no increase in cells or globulin. A roentgen examination of the legs presented no evidence of any pathologic changes of the bone. Staphylococci were found in a culture of the secretions. The basal metabolism was minus 34. A biopsy was made shortly before her discharge from the hospital. A marked infiltration of mucin throughout the cutaneous network was seen. Marked vacuolization was present and the elastic and collagen fibers were separated and displaced. Large numbers of stellate cells were observed. The epidermis was essentially normal.

Course—She was given 2 grains (0.13 Gm) of thyroid extract three times daily, and wet dressings of 1 3000 potassium permanganate were applied to the ulcerated areas. In five weeks these lesions, which had persisted unchanged for six years, had healed entirely. Her basal metabolic rate decreased to minus 8, and six weeks after her admission she was sent home. About one year after her discharge from the hospital she returned with similar ulcers on her left leg. The right leg remained completely healed. In a short while under the routine described the ulcers closed again, leaving only scars behind. In February, 1933 the ulcers occurred again in her right leg. Strangely enough the basal metabolism then was plus 40. Rest in bed and small doses of iodine brought the metabolic rate down to plus 1 and again the ulcers closed. This change from hypothyroidism to hyperthyroidism seems to be characteristic of these leg lesions and was noted and commented on by O'Leary,⁵ Pillsbury and Stokes,⁶ and other observers.

Differential Diagnosis—Eloesser¹³ states that leg ulcers are usually of three types: arteriosclerotic, infectious, or due to varicose veins. These conditions can be quickly eliminated in this case. The patient showed no sclerosis in other parts of the body and the blood pressure and kidneys were normal.

No varicose veins were seen and she showed no obvious focus of infection. Local antisepsis and rest in bed were never of any avail until glandular therapy was instituted. Syphilis could be eliminated on account of the family history, the negative blood and the spinal Wassermann reactions, and by the gross and microscopic pathologic appearance. The ulcers of erythema induratum were considered, but the clinical picture was not that described by Bazin. The edges of the ulcers had not undermined and the coloration was not blue or bluish red. Nor was there any evidence of tuberculosis in other parts of the body. The blood count excluded from consideration the ulcers of sickle cell anemia or a severe secondary anemia. Rare conditions that cause ulcerations—fungi, drugs and the like—can all be conclusively eliminated.

Even though staphylococci were found in the secretions the diagnosis of a pyodermic gangrenosa seems rather untenable. The disease is generally associated with anemia and colitis, neither of which conditions was present. The staphylococci were probably secondary invaders. The appearance of these ulcerations at the same time as the increase in size of the thyroid gland, the effective response to thyroid therapy, the changes in the basal metabolism corresponding to the clinical improvement of the legs leave no other diagnosis but that of ulceration of the lower extremities due to thyroid dysfunction.

COMMENT

This case arouses many interesting questions. In what way did the lack of the thyroid hormone aid in the production of the ulcers? Was this stage of deep ulceration an advanced stage from that of the so-called circumscribed myxedema described by the various authors already enumerated? Eppinger¹⁴ advances the theory that there may be somewhere in the organism a

Fig 2—Left leg six weeks after admission to the hospital, showing complete healing of the ulcers. The open lesion above the healed areas is the site of the biopsy.

barrier that prevents the thyroid hormone, of which there is no lack, from reaching regions lying beyond it—a local myxedema as distinct from a general myxedema, which is caused by a general lack of hormone. That thyroid hormone certainly plays a part in the healing of wounds is corroborated by the common

observation that wounds heal slowly in myxedematous patients. Accordingly, Eppinger¹⁴ applied thyroid extract locally in torpid cutaneous ulcers and obtained very good results. The local application of hormone products to wounds and ulcers is nothing very new, for the French, particularly, have been applying insulin to facilitate healing ever since insulin was discovered. Pautrier, Schmid and Ullmo¹⁵ report two cases of leg ulcers of long duration cured in two weeks by the application locally of insulin. However, other observers, prominently Nathan and Munk¹⁶ feel that the good effects are due to the acidity of the solution and not

to the specific reaction of the hormone. Eppinger explained his good results by the assumption that in the biologic exchange of fluid the quality of the membrane plays an important role. The surroundings of the wounds or ulcers may have been so injured that it is impermeable to the thyroid hormone, which is such an important factor in the regeneration of cells.

The presence of myxedematous symptoms in cases of hyperthyroidism seems rather anomalous. Most of the cases reported of circumscribed myxedema of the extremities occurred in exophthalmic goiter conditions following operation. In the case reported in this

exophthalmic goiter, comes to the fore and the hormone secretion reacts with hypothyroidism instead of with hyperthyroidism. Therefore, Richter believes that the paradoxical finding of myxedematous cutaneous symptoms in exophthalmic goiter has its explanation in a tertiary stage of exophthalmic goiter, which is hormonally associated with hypothyroidism.

It is nothing unusual to see patients going from physician to physician and from clinic to clinic complaining of severe ulcerations of the lower extremities which do not seem amenable to any treatment. A basal metabolism test might in some cases help to solve the problem and thyroid extract, used both internally and locally, might be very useful in healing some of these lesions. In every case of severe ulcerations of the lower extremities a careful physical examination and laboratory study should be made, for the majority of such disorders are due to systemic changes and not to local causes.

SUMMARY

1 This was a case of deep ulcerations of the lower extremities associated with myxedema.

2 The internal administration of thyroid extract quickly healed, in a few weeks, ulcers that had persisted unchanged for six years.

3 The cutaneous changes in diseases of the thyroid are not well understood or explained, and the relationship between circumscribed myxedema of the legs and leg ulcers of obscure etiology is suggested.

Clinical Notes, Suggestions and New Instruments

AN UNUSUAL CASE OF CARDIOSPASM

SAMUEL A. SHELBURNE, M.D. DALLAS, TEXAS

This case is reported principally because the esophagus was so dilated that it led to a clinical and roentgen diagnosis of fluid in the pleural cavity, and an aspiration of the esophageal fluid was made through the chest wall. This interesting clinical mistake has not heretofore been reported, as far as I have been able to determine from the literature. The case is interesting also because of the slight degree of dysphagia. This, of course, was a factor in forming the error in diagnosis.

L. W., a Negro, aged 35, admitted to Baylor Hospital outpatient department, April 19, 1932, stated that he had been working as a chauffeur and had been in fair health until February 26. On that day as he was riding on a street car, he felt a sudden pain in the pit of his stomach and he "broke out in a cold sweat." He got off and, after walking two blocks, he vomited about a pint of dark red—to black—fluid which he thought was blood. Since that time, he said, he had taken only liquids and a soft diet but within a half to one hour after almost every meal he had vomited a large amount of fluid. This had been present up until the time of admission. He said that he thought he had a little fever but no chills. He gradually grew weaker and, during the two weeks prior to admission, was confined to bed. He lost during that time about 40 pounds (18 Kg.). He said nothing about having any dysphagia when questioned at first, but later on leading questions led to the admission of some trouble in swallowing. He said that he had had some burning in his hands and feet during the last few weeks. The family history and past medical history were negative.

The patient was small and emaciated. He was apparently comfortable. The blood pressure was 102 systolic 68 diastolic. The pulse was 88, the temperature, 99 F. Examination revealed no changes except those found in the chest. There were flatness and diminished breath sounds at the right base up to the

Fig. 3.—Appearance of patient in February 1933 showing the enlarged neck and the scars of the healed ulcers on her legs.

paper the patient noted the return of her ulcers when the basal metabolism was high as well as when it was low. The presence of hypothyroidism and hyperthyroidism in the same patient at the same time is rather confusing and difficult to explain. Richter² quotes Kocher as assuming that exophthalmic goiter has three stages: a primary stage marked by intense symptoms, a secondary stage marked by a relenting and changing of the symptoms in accordance with the intervention of endocrine correlations, and a third stage characterized by regressive changes. Since all the parts of the thyroid and the other endocrine glands are not equally affected the clinical picture can vary enormously. Thus, for instance, part of the thyroid gland may return to a normal colloid condition, or the regressive changes may advance to such an extent that atrophy, which is ordinarily not a part of the histopathologic picture of

15 Pautrier, Schmid and Ullmo. Leg Ulcers in Patients Without Hyperglycemia Cured by Insulin Used as a Local Application. *Bull. Soc. franç. de dermat. et syph.* 33: 544, 1926.

level of the sixth dorsal vertebra. Tactile fremitus and voice sounds were also diminished. The heart was not enlarged, and the sounds were entirely normal. There were no rales at the apexes of the lungs. There was slight pitting edema of the feet. The reflexes were normal.

Tentative diagnosis was made of military tuberculosis with pleural effusion, or carcinoma of the stomach with pulmonary metastases. An immediate diagnostic aspiration in the mid-scapular line was made in the clinic. The fluid contained yeast cells and a few blood cells. An x-ray film of the chest revealed "a large encapsulation of fluid in the right mediastinum and the right chest." A lateral view was made later and a report was made of "encapsulated mediastinal pleurisy." A second tap was made and a large amount of fluid was recovered which had an odor of decomposed gastric juice. The patient was given barium by mouth which revealed that the so-called encapsulated fluid was really a hugely dilated esophagus (fig. 1). An esophagoscopy examination was made the fluid removed, and a diagnosis of cardiospasm established.

There were no ill effects following the aspiration probably because the dilated esophagus was approximated so closely to the chest wall that no leakage occurred. The patient was treated by hydrostatic dilatation and he immediately began to gain weight. Later on it was found necessary to do a gastrostomy.

Fig 1—Anteroposterior view of chest showing enormously dilated esophagus full of fluid. It was into this sac that the puncture was made.

Fig 2—The same after ingestion of barium.

Fig 3—The same after a large amount of fluid had been aspirated from the esophagus.

Since that time he had gradually increased his weight up to his usual normal. A prognosis for complete restoration of the esophageal function is not good, for he is having considerable difficulty at the present time in swallowing his food and it is still necessary to feed him through the gastric stoma.

Medical Arts Building

BILATERAL NECROSIS OF THE CORNEA FOLLOWING THE USE OF HAIR DYE ON THE EYEBROWS AND LASHES

CHARLES T. MORAN, M.D. ARKANSAS CITY, KAN.

There have recently been a number of case reports demonstrating the harmful results following the use of hair dye on the eyebrows and lashes. I am presenting this case not to advocate any type of treatment but merely to add one more case to the already fast growing list and to impress the importance of determining whether or not a person is sensitive to a particular dye before using this harmful procedure.

This case report concerns a woman aged 66, who has had her eyebrows and lashes dyed many times. On April 15, 1933, she used a new preparation known as the Godefroy French Hair Coloring (L'arouse) which contains paraphenylenediamine. Immediately afterward her eyes began to itch. She consulted me three days later at which time she had a conjunctivitis. I prescribed for her and did not see her again for two days.

During this time the itching became more intense, both eyes became swollen shut, and her face became red and edematous from the hair line down to the chin. At first glance it looked similar to a facial erysipelas. It was very difficult to see the corners, owing to the large amount of palpebral and bulbar chemosis and photophobia, but they apparently were clear.

A dermatologist was called in consultation and he prescribed for the skin condition. A dermal test with the dye resulted in a four plus reaction. The swelling continued, and one week later a small corneal ulcer appeared at the limbus of the right eye at 6 on the clock dial. The pupils were dilated with difficulty by means of homatropine and then 1 per cent atropine. The ulcer was first cauterized with phenol and alcohol and it did not improve. Two days later a hypopyon appeared. The patient was then hospitalized and the ulcer cauterized with the actual cautery. In spite of all types of treatment, including foreign protein therapy and typhoid vaccine intravenously, the ulcer progressed and perforated.

All this time a careful watch was kept on the left eye. The following day, after the perforation of the right cornea, during the afternoon while the special nurse was away, an intense itching of the left eye suddenly occurred and the patient rubbed her eyes severely. Her forehead and lids at this time were somewhat improved, which I believe was due to shaving the

brows and clipping the lashes. That evening an ulcer developed on the left eye and the whole corneal epithelium was denuded by the next morning. The margins were cauterized with the actual cautery and a Kuntz conjunctival flap was pulled over the corner. Typhoid vaccine was again administered.

The progress was slow, the flap came off in four or five days and the ulcer was beginning to heal from the periphery. The margins were cauterized a number of times. In two or three weeks the ulcer was very small. July 4, after two weeks at home, the patient went about feeling better. Atropine had been discontinued for some time, because of atropine poisoning. Intense pain suddenly developed in the left eye. The tension was increased to digital palpation (I was unable to use a tonometer because of the corneal ulcer) and could not be reduced with physostigmine so an iridectomy was done, which has controlled the tension to date.

I last saw the patient November 1. She could see fairly well and could walk about the room. Her vision had improved rapidly in the past month, it being 10/200. I feel that this will increase as time goes on. She is using ethylmorphine hydrochloride, 5 per cent, three times a day.

COMMENT

1 The patient was particularly sensitive to paraphenylenediamine, as a scratch test was done on the arm, which produced a large erythematous area.

2 The ulcer on the right eye was very malignant and resisted all types of treatment.

- 3 I believe that the removal of the lashes and brows did more to alleviate the dermatitis than any other type of therapy
 - 4 The application of the conjunctival flap was a great factor in saving the left eye
 - 5 If the patient had been tested before the application of the dye, this pathetic condition could have been avoided

CLINICAL CONTROL OF CHRONIC HEMORRHAGIC STATES IN CHILDHOOD

I NEWTON KUGELMASS, MD
NEW YORK

(Concluded from page 210)

VASCULAR HEMORRHAGIC DISEASES

Hemorrhagic symptoms abound in disturbances of the vascular channels. Their integrity may be altered structurally or functionally with consequent escape of normal blood. Vascular structure may be affected externally by trauma and internally by increased pressure, by lack of nutritional elements, by bacterial invasion, by chemical injury and by lymphatic infiltration. Occasionally an infant is born with defective vascular structure in one part of the body or another. Again, vascular function may be influenced by internal secretions, by allergic substances and by infectious agents. Although structural changes necessarily disturb vascular function, the one group of hemorrhagic disturbances may be differentiated from the blood etiologically on the basis of extravasation of blood on

Fig 8—Proliferation of intima and separation of elastic interna in scurvy

the one hand and blood combined with exudate inflammatory changes on the other. Such clinical differentiation offers direct therapy on the basis of the etiologic factor interfering with vascular integrity.

The methods of studying the status of the child's vascular endothelium are as yet very crude but clinically accurate. Diminished capillary resistance may be determined by the tourniquet test yielding petechiae or hemorrhages, or it may be gleaned from the diminished urinary output in the erect posture in the presence of pathologic changes of the capillary system. It may be observed microscopically from capillary nail beds revealing structural changes. My determination of the

presence of vascular pathologic changes, however, is made indirectly when blood studies show normal content of clotting constituents. Thus are the vascular problems, strictly speaking, nonhemorrhagic diseases.

1 Hemorrhagic Avitaminosis—R N, an infant girl, aged 4 months, was admitted for treatment of nutritional atrophy. Born at full term of an emaciated mother, the baby was maintained on very dilute boiled milk mixtures at irregular intervals with indiscriminate care. After gradual adjustment of concentrated feedings, the baby nevertheless failed to thrive. There were no evidences of enteral or parenteral infection. The blood Wassermann reaction and roentgenograms of the long bones were negative. Petechiae, first observed in the mucous membranes, spread until purpuric spots covered the body. The blood picture before transfusion showed hemoglobin 70 per cent, red blood cells, 3,800,000, white blood cells, 14,000, lymphocytes, 55 per cent, platelets 180,000, tourniquet test, positive, clotting index, 0.45. The purpura was unaffected by transfusion but cleared gradually with vitamins A, B, C and D reinforcing the feeding regimen. Vitamin deficiency produces capillary degeneration. In this case nutritional deficiency preceded birth and was particularly striking in the paucity of these vitamin factors in both the mother's and the baby's food. The blood showed no evidence of hemorrhagic disease but the purpura was a result of vascular injury resulting from vitamin deficiency.

Fig 9—Microscopic section of a capillary bed in allergic purpura

Scurvy is a classic example of the specific relation of vitamin C to hemorrhage. The primary disturbance is a separation of the cement substances binding the vascular endothelium cells. It is only in severe cases that bone marrow atrophy is produced with subsequent diminution in platelet formation. In children, the external vascular phenomena bespeak the typical clinical picture. And their manifestations are latent and elusive early in the deprivation of vitamin C in the dietary. So much emphasis has been placed on the rôle of vitamin C in the vascular hemorrhage that others have been neglected. Fanconi demonstrated that hemorrhagic symptoms in children with Herter's infantilism are a consequence of vitamin deprivation. Others have observed similar phenomena in the course of marasmus. Apparently, the nutrition of the vascular endothelium depends largely on the vitamin adequacy of the dietary.

2 Allergic Purpura—A L, a boy, aged 5 years, had recurrent attacks of colic since infancy. They usually occurred during the spring with pain in the abdomen and musculature followed by tarry stools with mucus. All treatment was refractory each episode being self limited. At the fourth year the attack was so severe that the appendix was removed. When he came under my observation during an attack, the boy showed infected tonsils, carious teeth and intense dermatographia. The blood picture showed a hemoglobin of 80 per cent, red blood cells 3,800,000, white blood cells 17,000, platelets, 270,000, clotting time five minutes, bleeding time, four minutes, tourniquet test, positive, polymorphonuclears, 74 per cent, eosinophils, 5 per cent. The urine showed albumin, casts and red blood cells. The parents were both allergic. The removal of carious teeth, tonsillectomy and gradual desensitization with a nonhemolytic streptococcus obtained from a culture of the tonsils prevented these attacks thus far for two years.

Systemic hemorrhagic attacks recurring in allergic children are well defined syndromes. The tissues affected by hemorrhage have previously been differentiated as separate syndromes, gastro-intestinal hemorrhages as Henoch's purpura, joint involvement as Schoenlein's purpura, and cutaneous eruptions as erythema multiforme, but the advent of the allergic mechanism has unified these syndromes into a single group of allergic purpura. They are usually the result of bacterial, food or drug allergy in children of allergic

Fig. 10—Section showing destructive inflammatory lesion in a vein in syphilis; cluster destroyed lumen of vessel occupied by new formed vessels, giant cells, endothelioid cells and plasma cells.

constitution and parentage. The purpuric eruptions usually follow generalized symptoms which together constitute the recurring pattern for the particular child. The blood-clotting function is normal, but the capillary resistance is varied in the same patient. Once the diagnosis is determined, recovery is spontaneous and prognosis is always favorable.

Prevention of recurrent allergic purpura requires the discovery of the specific allergic offense. In the case of Henoch's purpura cited, the elimination of the oral foci of infection cleared the condition. In another case, that of a girl, aged 5 years, purpuric spots appeared over the legs with each attack of tonsillitis. Tonsillectomy was performed on the basis of a supposedly rheumatic fever and postoperatively petechiae and joint pains recurred. When the child was first presented a diagnosis of Schoenlein's purpura was made. The persistence of a hemolytic streptococcus in the sinuses was the focus responsible for the exacerbations. Desensitization with a specific vaccine eliminated the allergic purpura. Another girl, aged 8 years, showed for two years recurrent attacks of abdominal cramps, joint pains and purpuric spots over the legs. Since there were no foci of infection, skin tests were made. On that basis wheat, egg yolk and pork were eliminated, with complete disappearance of symptoms except for the purpuric eruptions. The accidental inclusion of an egg-containing food precipitated allergic symptoms. Clinical variations of allergic purpura are innumerable. Patients with recurrent attacks are treated for indigestion, rheumatic fever, purpura and sepsis and are operated on for appendicitis, intussusception or gastric ulcer before the actual diagnosis is established. But the attacks continue until the allergic offense is eliminated.

3 Hemorrhagic Infections—H. R., a boy, aged 4 years, was admitted to the hospital with a history of convulsions associated with a severe infection of the upper respiratory tract. Hemorrhage appeared in the orbit and marked purpuric extravasations over the trunk and upper extremities. Facial weakness and complete right hemiplegia followed. Examination of the blood showed clotting and bleeding time, normal, tourniquet test, positive, platelets, 310,000, platelet lysis, 35 per cent, and blood clotting function normal. An encephalitic infection was the cause of the purpura.

Hemorrhagic symptoms predominate in infectious invasion. Vascular injury usually exceeds the disturbances in myeloid function, but the relative changes in each depend on the severity of the infection. I have observed as confirmation of the vascular injury petechiae containing the organisms of meningococcemia, embolic abscesses with visceral hemorrhages in pneumococcemia, nosebleeds and even hemorrhagic sputum in epidemic influenza, thrombotic petechiae consisting of tuberculi, punctate hemorrhages in scarlet fever, bleeding of the mucous membranes in diphtheria, hemorrhages from the mucous membranes in congenital syphilis and purpura associated with the presence of endothelial cells in the circulating blood of subacute bacterial endocarditis.

Capillary hemorrhages are not infrequent as consequences of vascular congestion in the course of chronic infections. Rheumatic heart disease induces epistaxis or congestion hemorrhages in the edematous lower extremities. Pertussis precipitates hemorrhages into the conjunctivae and eyelids as well as from the nose and bronchi. Uremia occasionally reveals terminal cerebral, retinal and intestinal hemorrhages rather than petechiae. The hemorrhagic symptoms in uremia parallel the severity of capillary damage from infection and not the degree of nitrogenous retention. Increased venous pressure in normal circulatory systems is not a determining factor in these bleeding manifestations.

Arrest of bleeding in the course of infectious invasion may be brought about by therapeutic measures for decreasing capillary permeability. Elimination of infec-

Fig. 11—Proliferative phlebitis of a large vein in peritonsillar tissues in scarlet fever.

tion is of course, the primary concern, but the self-limited nature of infectious disease necessarily requires vascular medicaments. Clinically, calcium salts have been used in most hemorrhagic diseases for centuries with favorable effects but based on erroneous interpretations. The calcium required in the clotting mechanism is rarely found wanting in amounts necessary for this process. Even the striking clinical entities involving hypocalcemia never show bleeding symptoms. Calcium therapy is indicated in abnormal bleeding resulting from vascular dysfunction. Its effect is spe-

cific in decreasing capillary permeability. The calcium salts administered have no bearing whatever on elevating the well buffered calcium content of the blood. Calcium therapy is best administered intravenously in a 10 per cent solution of calcium gluconate or calcium chloride from 10 to 25 cc injected very slowly. Oral administration is of course slower in its effect but may well be supplemented in from 5 to 10 gram (0.33 to 0.65 Gm.) doses offered between feedings to prevent its precipitation into the intestinal tract and subsequent loss in the stools.

The administration of gelatin arrests bleeding by condensing platelets on the vascular bed. From 20 to 40 cc may be injected intravenously in 10 per cent solution, or it may be fed in 10 per cent solution, either directly sweetened and flavored with vanilla and mixed with milk, or as a jelly, which may be kept on ice for two days.

Solution of pituitary is an effective vasoconstrictor in arresting bleeding. This mechanism is operative in vascular beds other than those of the female genital organs. The injection of 0.5 cc of solution of pituitary frequently suffices to arrest capillary oozing when due to vascular injury. The action is more prolonged than that of epinephrine hydrochloride. It is the vasopressor fraction of the posterior lobe that affects the vascular endothelium in the direction of increased blood coagulation.

HEREDITARY HEMORRHAGIC DISEASES

Hemorrhagic tendencies may be truly inborn. They are the consequence of hereditary defectiveness rather than symptoms of disease. In no other ailment is the medical history of previous generations as significant as in the transmission of hemorrhagic defectiveness. And its manifestations are so dramatic as never to be forgotten by any family. Teleologically there exist genotypes with transmitted defects in the formation of each of the clotting factors, sex-linked defectiveness in platelets in hemophilia, familial abnormalities in platelets in thrombasthenia, congenital derangement in fibrogen formation in fibropenia, familial defectiveness in vascular channels in telangiectasis. Thus may each of the factors involved in the clotting mechanism be formed defectively throughout life as a family failing. But these constitutional familial hereditary diseases are not always clear cut, for nature's defects are never

in the bone marrow, spleen, liver and capillaries. Therefore all the more caution is necessary in the diagnostic finality of hereditary hemorrhagic tendencies.

Fig. 12—Transmission of hemophilia

TABLE 4—Hereditary Hemorrhagic Diseases

	Hereditary Transmission Through	Sex	Site of Bleeding	Blood Picture	Clinical Control
Hereditary hemophilia	Mother	Male	Mucous membranes skin joints	Platelets stable clotting time prolonged	Locally Raw meat fresh blood Intradermally Goat serum Intramuscularly Ovarian extract anterior pituitary Intravenously Transfusion
Familial thrombocytopenic purpura	Parents	Male female	Mucous membranes skin	Platelets diminished bleeding time prolonged clotting retraction delayed tourniquet test positive	Orally Clotting diet calcium salts Locally Fresh blood Bodily Ultraviolet irradiation Intram Blood calcium gluconate Intravenously Transfusion Surgically Splenectomy
Hereditary thrombasthenic purpura	Mother	Male female	Mucous membranes	Platelets stable bleeding time prolonged clotting retraction delayed tourniquet test positive	Locally Fresh blood Intravenously 10% calcium salts 10% gelatin transfusion Intramuscularly Ovarian extract Local Cauterization defective vessel Intravenously Transfusion
Hereditary hemorrhagic telangiectasis	Parents	Male female	Mucous membranes defective nasal buccal gastric uterine rectal	Normal	

selective. Obviously combinations of hemorrhagic defectiveness exist as phenotypes of the well defined hereditary diseases. Clinically, even hereditary diseases are the result of disturbances existing simultaneously

1 Hereditary Hemophilia—A H a boy aged 8 years bled from infancy with every disturbance. The mother's oldest brother was a bleeder. Continuous bruising followed slight trauma since walking. A large hematoma of the leg followed

an insect bite. An abrasion of the lip oozed for ten days. A slight laceration of the hand from cut glass on falling bled for days in spite of the administration of tetanus antitoxin. But a transfusion from the mother promptly arrested the bleeding. Hemorrhagic effusions into the left knee joint recurred until whole blood was administered from the mother at her menstrual period. Bruises continued following trauma but bleeding ceased after fortnightly injections of ovarian extract intramuscularly and goat's serum intradermally.

Hemophilic bleeding can be controlled but not cured. Mild bleeding may be stopped locally by application of fresh raw meat, fresh blood or cephalin after the removal of useless clots; pressure alone is contraindicated. All other hemostatics locally applied are ineffective. Severe bleeding may be checked for four days by the transfusion of whole blood from a suitable donor. Even an ounce of injected blood arrests hemorrhage, but the degree of subsequent improvement depends on the amount of blood given. Stored serum is ineffective in inhibiting clotting, but an ounce of fresh serum arrests bleeding within a day.

Hemophilia is as characteristic clinically as it is hematologically. It occurs in the male with a typical familial bleeding pattern. It is transmitted by the female, although the mother's blood shows a normal blood-clotting function. Bleeding is protracted, the clotting time prolonged and, paradoxically, the bleeding time normal. Hemophilic blood shows the lowest index of blood-clotting function and a normal or increased number of platelets, physiologically defective because of their striking stability. Capillary resistance tests reveal no impaired function.

Bleeding from superficial injuries may be diminished by passive sensitization. The maintenance of an allergic state by repeated serum therapy increases the prothrombin sufficiently to be protected by capillary hemorrhage following trauma. In fact, the clotting time of capillary blood is diminished within two hours of the injection of serum. But the change produced in the blood is inadequate against injuries involving the larger vessels and joints. The child is sensitized preferably to goat's serum by the subcutaneous injection of 3 cc. At the end of a fortnight, the child is given from 2 to 3 minims (0.12 to 0.18 cc.) of the serum intradermally. The appearance of a wheal at the site of injection indicates passive sensitization. The intradermal injection of the same serum should be repeated every two weeks for the maintenance of the allergic state. Another procedure effective in arresting hemorrhage in emergency is a transfusion of blood from a donor sensitized to goat's serum. The intradermal injection is repeated every fourteen days to continue sensitivity in the hemophilia.

Bleeding into the joints may be controlled by ovarian hormone therapy. Most hemophilic patients bleed from the mucous membrane of the nose, mouth and gums

and into the joints. Other sites of hemorrhage are relatively infrequent in comparison. And no form of therapy thus far advanced has been as effective as the injection of female sex hormone. Its absence in the blood of tissues of hemophilic boys is a hereditary sex-link deficiency factor. Its administration weekly produces no changes in the concentration of clotting substances but rather decreases capillary permeability. Injection of active ovarian extract is indicated for interim treatment of the hemophilic state rather than for control of acute hemorrhages. Repeated intramuscular injections decrease the bleeding tendency without affecting the easy bruising. Acute joint lesions require splinting and even immobile plaster of Paris

TABLE 5—Therapeutic Measures for the Arrest of Bleeding

Procedure	Platelet Deficiency	Fibrinogen and Thromboplastin Diminution	Vascular Disturbance
Local	Extract of blood platelets; ultra violet irradiation	Thromboplastin; meat juice	Shepherd's pure
Oral	Mosterol	Cephalin; fibrinogen	Calcium salts
Nutritional	Dietary fat (unsaturated lipids)	Dietary protein (gelatin viscera)	Ba e-forming foods
Intramuscular	Forelin protein	Blood serum	Pituitary, parathyroid extract
Intravenous	Transfusion	Transfusion	10% calcium salt; 10% gelatin

bandages until pain disappears and the hemorrhage is absorbed. Aspirations are contraindicated. Chronic hemophilic arthritis requires correction of deformities. Traction or wedging plasters or mechanical appliances stretch the contracted tissue and strengthen the joint. When the limb is kept in the corrected position by an elastic bandage

The prevention of hemophilia is a problem for eugenics. The course of the disease can be altered. Nature spares hemophilic new-born infants from the effects of birth trauma by the transmission of an abundance of female sex hormone into the infant's circulation. Thus it is that the disease does not become manifest until late in infancy unless surgical intervention precipitates bleeding. The disease tends to ameliorate with growth, particularly after the endocrine adjustment of puberty. The avoidance of trauma by limitation of activity requires compensatory physical therapy to improve muscle tone. The maintenance of bodily warmth and vacations in warm climates appear, in addition, to alter favorably the course of the disease. The clotting dietary has produced no appreciable effect on the hemorrhagic status of hemophilic persons. Infection has been found to precipitate bleeding, particularly into the skin and joints. Operative emergencies are safely

Fig. 14—Vascular varicosities with hemorrhage in hereditary telangiectasis

carried out after preliminary transfusion

2 *Familial Thrombocytopenic Purpura*—J C, a boy, aged 14 years, had suffered severe nosebleeds since infancy. His mother's maternal uncle and grandfather and two sisters were similarly affected. No other form of bleeding occurred, but the epistaxis recurred regularly during the winter months. During the period of an infection of the upper respiratory tract, nosebleeds became more persistent, not infrequently being associated with petechiae in the conjunctiva and palate. There was no evidence of telangiectasis in the upper respiratory tract. The nail fold capillaries were tortuous. The spleen was never felt. The blood picture was normal, the platelets fluctuating around 110,000, bleeding time was twelve minutes and clotting time four minutes, clot retraction was delayed, the tourniquet test varied. The boy was maintained on a high fat and protein dietary with some benefit. Early treatment of infectious invasion minimized several attacks of epistaxis. Irradiation by ultraviolet light reinforced by 10 D cod liver oil and calcium salts during the winter months contributed toward the elimination of these attacks. A donor for intramuscular and intravenous therapy was available but not used.

Essential thrombocytopenic purpura may be a constitutional disturbance characterizing certain families. Cases have been reported in infants of both sexes born of mothers with this disease. In fact, some of the infants have shown multiple malformations in other tissues of the body and some have shown striking deficiencies in megakaryocyte formation. Intravenous transfusion is effective if repeated, but intramuscular blood is of little avail. Splenectomy is a surgical risk in new-born infants. Of those that survive, recurrent bleeding persists more or less throughout life. There is always a hereditary history, its transmission being a dominant characteristic, and the pattern of bleeding simulates the affected members of the family. The basis of the bleeding is thrombocytopenic and, unless medical supervision minimizes bleeding, splenectomy is indicated.

3 *Hereditary Thrombasthenic Purpura*—B W, a girl aged 10 years, had spontaneous hemorrhages since infancy. Her mother had had recurrent epistaxis and mild purpura throughout her life, but none of the older children were affected. The child would suddenly develop severe nosebleeds or ecchymosis over the head, neck and extremities without any apparent exciting cause. At 7 years, a loosened tooth followed bleeding of the gums for two weeks. At 8, a vaginal hemorrhage stimulated menstruation. She was variously treated for purpura and hemophilia. The hemoglobin was 55 per cent, red blood cells 3,100,000, white blood cells 7,800 polymorphonuclears, 71 per cent, monocytes, 15 per cent, lymphocytes, 12 per cent, platelets, 395,000, clotting time, six minutes, clot retraction, delayed. Bleeding time from the right ear lobe was ten minutes, left ear lobe, thirty-two minutes, the tourniquet test was positive. Bleeding was arrested locally by means of tampons saturated with fresh blood obtained from the father. Only repeated intravenous transfusions were effective in aborting the duration of spontaneous hemorrhages.

Children may be born with hemorrhagic purpura without thrombocytopenia. It is transmitted by the mother to both sexes. Recurrent bleeding may be spontaneous or traumatic. The blood picture is normal, excepting for the changes incident to the simple loss of blood, but the platelets are always normal in quantity but defective in quality. They show abnormalities in size, shape and staining qualities with consequent failure of agglutination. Therefore the bleeding time is prolonged, clot retraction is retarded or absent and the tourniquet test is positive. Therapy is based on procedures for supplying normal platelets only possible by intravenous transfusions. All other platelet therapy is ineffective and splenectomy is useless. Recently I have

found the administration of theelin particularly effective in accelerating platelet agglutination.

I have witnessed death following splenectomy in a 10 year old girl with this condition. Like her mother, she had had recurrent epistaxis and purpura since birth. Her blood picture was characteristic of thrombocytopenic purpura, but a neglected hemorrhage became uncontrollable when splenectomy was performed. I followed the course of this disease in two brothers whose mother experienced milder purpuric bleeding. One boy had hemorrhagic measles. Both boys responded well to protection from trauma, prevention from infectious foci, early arrest of purpuric symptoms and repeated transfusions before bleeding became uncontrollable.

4 *Hereditary Hemorrhagic Telangiectasis*—J G, a girl, aged 13 years a twin, developed repeated nosebleeds. The other twin was normal, but the grandmother, paternal uncle and nephew had similar attacks. Examination of the blood showed hemoglobin, 60 per cent, red blood cells, 4,000,000, white blood cells, 8,500, polymorphonuclears, 65 per cent, platelets 280,000, clotting time, three minutes, bleeding time, five minutes, clot retraction, three hours, tourniquet test, negative. Examination of the nasal and mucous membranes showed multiple angiomata as the local cause for bleeding.

Puberty first precipitates bleeding varicosities which characterize this developmental effect. It is transmitted by both sexes and affects both. Inherited defects in the venous channels are usual in the nasal and buccal mucous membranes but hemoptysis, gastric hemorrhage, uterine bleeding, hematuria and even rectal bleeding may result from such telangiectases. The blood picture is normal and so there is no excessive bleeding or bruising from other sites of the body excepting from the dilated vessels. The treatment is local and as yet not specific.

5 *Transitional Hereditary Hemorrhagic Diseases*—H C, a boy, aged 14 years, gave an unusual hemorrhagic picture. The family was free from hemorrhagic heredity. Recurrent nosebleeds from infancy alternated with purpuric eruptions, joint lesions and hematuria. On examination, the boy showed petechiae of the mucous membranes, ecchymosis over the extremities and acute hemarthrosis. Examination of the blood showed hemoglobin, 70 per cent, red blood cells, 4,000,000, white blood cells, 5,900, polymorphonuclears, 70 per cent, lymphocytes, 20 per cent, platelets, 450,000, clotting time, eighteen minutes, bleeding time, forty minutes, clotting retraction, positive, tourniquet test, positive.

Such is the blood picture of an atypical hemorrhagic problem. It conforms both to hemophilia and to thrombocytopenic purpura. It demonstrates the futility of following pattern pictures for diagnostic nomenclature. Hemorrhagic patients respond to proper measures corrective of their disturbance rather than to those traditional treatments accorded to the disease label. In no other disease mechanism is individualization of diagnosis and treatment essential. Among the chronic hemorrhagic disturbances exist entities intermediate between the so-called primary hemorrhagic diseases. Hemophilia is etiologically an endogenous disease of certain mesenchymal structures, as are the purpuras, thrombocytopenic and thrombasthenic. Hence, combinations of such defectiveness exist simultaneously in these tissues, giving rise to chronic transitional disturbances. Observation of such cases has contributed as much to a clinical conception of hereditary heterogeneity as to the creation of corrective measures in their behalf.

1060 Park Avenue.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONTRIBUTING TO THE FULFILLMENT OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS, D. D., Secretary

ANTIRABIC VACCINE (See New and Nonofficial Remedies 1933 p 571)

The National Drug Co. Philadelphia

Rabies Vaccine Human (Simple Method) (See New and Nonofficial Remedies 1933 p 373) — Also marketed in set of two packages the first containing four 2 cc vials and the second containing ten 2 cc vials.

DIPHTHERIA TOXOID (See New and Nonofficial Remedies 1933 p 384)

The National Drug Company, Philadelphia

Diphtheria Toxoid (See New and Nonofficial Remedies 1933 p 384) — Also marketed in packages of ten immunization treatment consisting of twenty 1 cc vials each containing one human dose.

ANTIMENINGOCOCCUS SERUM (See New and Nonofficial Remedies 1933 p 367)

The National Drug Company, Philadelphia

Antimeningococcus Serum — Marked in packages of two 15 cc double end vials with apparatus for intrajugal injection, in packages of one 15 cc cylinder with intrajugal needle and in packages of one 30 cc double end vial with special intravenous and intraspinal needles and gravity outfit.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS

RAYMOND HERTWIG, Secretary

NOT RECEIVED

WELCH'S CERTIFIED PURE PASTEURIZED GRAPE JUICE

The Welch Grape Juice Company of Westfield, N. Y., submitted to the Committee on Foods a bottled pasteurized grape juice, slightly sweetened with sucrose called Welch's Certified Pure Pasteurized Grape Juice.

Preparation — The grapes are washed, crushed, stemmed, heated to 57° C and pressed, the juice slightly sweetened with added sucrose is heated to 88° C and filled into 5 gallon carboys which are sealed and stored for three months during which considerable cream of tartar settles out along with some organic matter. The supernatant juice is siphoned out, heated, filled into bottles and pasteurized.

Analysis (submitted by manufacturer) —

	per cent
Moisture	82.3
Total solids	17.7
Ash	0.3

Protein (N x 6.25)	0.5
Reducing sugars as invert sugar	15.1
Nonsugar solids	2.6
Total acids as tartaric	1.0
Pigment and coloring matter	0.5
Potassium bitartrate (cream of tartar)	0.4

Calories — 0.6 per gram 17 per ounce

Discussion of Ad Claims — Recent advertising announced this grape juice as a discovery of modern science for weight reduction and the burning up of fat. The following examples illustrate the type of claims used.

Modern science discovers Welch Grape Juice burns up fat. Get thin the new way. Drink Welch's and keep your gushy figure. Welch's simple grape sugars are quickly absorbed and used and hence not stored as fat. Its non-fattening grape sugar forces the body to burn up its fat. Strive slender drinking Welch's. Famous food authority says Welch's should be on every reducing diet to insure healthful reduction. This new method takes advantage of the amazing health properties in Welch's Grape

Juice. For years the grape cure has been prescribed by the most eminent European doctors as the ideal method of healthful weight reduction. It has now been shown that Welch's Grape Juice contains all the elements of the grape useful for weight control. In order for fat to burn there must be available to the tissue easily burnable predigested non-fattening grape sugar in Welch's Grape Juice. Taken with proper diet fat disappears. You're going to take the Grape Cure, the accepted weight control formula. Its natural potassium removes unnecessary water from the body's tissue. Welch's contains more of the essential energizing elements than any other popular fruit juice.

The claims would falsely lead the reader to believe that Welch Grape Juice has specific properties for reducing weight. This grape juice is no more effective for reducing weight than are many other common foods. It does not 'burn up fat' and its sugar chemically plays the same part in fat metabolism as does any other available carbohydrate. The advertising naïvely makes it appear that it is the grape juice in reduction diets which brings about weight reduction and not the controlled diet as a whole. The sugars of grape juice may be stored as fat under proper conditions as are any sugars or other carbohydrates. Its sugar in no sense 'forces the body to burn up its fat.' The much ado about the grape sugar being predigested has no significance.

Drinking Welch's Grape Juice does not assure slenderness as stated or implied, but may increase weight. One glass furnishes 143 calories. No 'famous food authority' can truthfully or authoritatively say that 'Welch's should be on every reducing diet to insure healthful reduction.' This grape juice will not keep [one] healthy nor will its 'natural potassium' remove unnecessary water from the body's tissue. Healthy tissues do not contain unnecessary water. The product has no amazing health properties or any specific 'health properties' at all. Its nutritional values are limited. A reducing diet containing grape juice is no 'grape cure.' Welch's Grape Juice is not significantly different from any other good grape juice.

The advertising claimed that this grape juice has special blood building power. It appealed

to mothers of run-down children (who are) thin as a rail (who) suffer dreadfully from indigestion (are) who is a sheet (who's) teeth are soft. It stated that Welch worked wonder with June. It contains more vitamin B than orange juice. It is superior to it as a hemoglobin or red corpuscle restorative. In countless homes Welch's is helping run-down children build muscle and bone, make rosy cheeks and buoyant energy. If your children just pick at their food refuse to eat, don't wait, buy a bottle of Welch's. Start them with a glass for breakfast then once or twice during the day and again before bedtime. In a very short time you will see wonderful results. Be sure to insist on Welch. It is the Welch process that retains in the juice the healthful properties of grape so essential to the system. A noted food authority has shown that Welch compares favorably with mother milk in protein content (body building material) and also iron, calcium, phosphate and magnesium, so essential for growing children. Because of the properties physicians recommend Welch's Grape Juice as the key element in the build-up diet of the child. It contains two elements which are essential to the health of your child: sugar, protein and calcium and phosphorus. As a Regulator Welch's Grape Juice contains minerals, water and vitamins natural to the grape which facilitate the elimination of waste products from the intestinal tract, aiding digestion, absorption, elimination and also reducing food putrefaction and holding them [foods] in solution in the blood and carrying waste products from the tissues to be eliminated by the lungs, kidneys, skin and intestines. Welch contains vitamin B necessary to normal appetite to vigor. The absence of vitamin B from the diet is a cause of neuritis or nerve disintegration, dyspepsia, constipation and other intestinal troubles. The advertising questions: Is this not true of other grape juices also? To this question we must answer: Perhaps. But perhaps has no place in the diet of children. It entices [children] into taking sufficient water, seriously lacking in the diet of so many children and the unsuspected cause of countless disorders and deficiencies. It assists metabolism or assimilation of other foods. Women at those periods when they are troubled with nausea expectant and nursing mothers who need an additional mineral supply find Welch's invaluable. It contains no water and above all no tartaric acid. For many years specialists have recognized the value of Welch's Grape Juice as an aid to quick recovery from wasting illness. Hospitals and medical specialists have long valued Welch's in treating intestinal troubles. Especially is it valued in stomach and nervous disorders whenever the digestive system cannot or will not handle other foods. It is difficult to write of Welch's without dwelling long on its wonderful medicinal and dietetic values.

The claims are either flagrantly incorrect or misleading. Many commonplace foods of the table are so far greater importance for improving run-down children. Grape juice has no

value for building muscle or bone. Welch's will not revive lost appetites nor is it important for contributing vitamin B for normal appetite. Welch's has no value as implied for preventing the stated disastrous results of a vitamin B free diet nor has it any wonderful medicinal and dietetic values. It is not different from any good grape juice. No rational noted food authority would in any manner compare Welch's with mother's milk for popular advertising purposes. These two foods are as utterly unlike in nutritional values as in appearance and flavor. Welch's is anything but the key element in the "build up" diet of the child. It is essentially a pleasingly flavored sugar solution, ranking with *cater* for "facilitating elimination of waste products, aiding digestion absorption, and reducing food putrefaction." Children normally drink enough water to avoid safely unsuspected "countless disorders and deficiencies due to possible lack of water. Expectant and nursing mothers cannot derive their needed additional mineral supply from Welch's.

Many other types of crudely ludicrous and misleading claims of the advertising are not listed here because of space limitations.

This advertising is manifestly an artfully designed piece of deception to entmesh the credulous and those uninformed in nutrition and physiology. It is a hodgepodge of nutritional and physiologic chicanery, falsities, vagaries, juggled and distorted facts, misrepresentations and claptrap claims. It is a revival of the blatant "patent medicine and nostrum blarbs of the past. The advertising treats an ordinary food as a therapeutic and weight-reducing agent, which it is not.

Perversions of advertising of this character bring good advertising into disgrace and disrepute and unfortunately harm the majority of the food trade that conscientiously attempts to deal fairly.

The company, when informed of the Committee's opinion, has not expressed willingness to change the advertising. This brand of grape juice, therefore cannot be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary

BEECH-NUT BRAND STRAINED BABY SOUP (Slightly seasoned with salt)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Strained vegetable soup prepared from tomatoes, carrots, celery, cabbage, barley, rice, salt and a small amount of onion retaining in high degree the natural vitamin and mineral values.

Manufacture—Carrots, celery, cabbage and onions are washed by hand and the carrots scraped. All are cut fine. Definite proportions of rice and barley are cooked for one half hour. The vegetables, salt and a little water are added. The cooking is in a glass lined kettle in an atmosphere of steam. The material is strained, canned, sieved tomatoes are added and the composite is vacuumized and standardized for consistency. The subsequent treatment and processing are the same as for Beech-Nut Strained Carrots (THE JOURNAL Nov. 11 1933 p. 1562).

Analysis (submitted by manufacturer) —

	per cent
Moisture	88.9
Total solids	11.1
Ash	1.0
Sodium chloride	0.5
Fat (ether extract)	0.0
Protein (N X 6.25)	1.0
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	8.0

Calories—0.4 per gram, 11 per ounce

Claims of Manufacturer—See Beech-Nut Strained Carrots (THE JOURNAL Nov. 11 1933 p. 1562)

ROSE BRAND UNSWEETENED EVAPORATED MILK

Manufacturer—The Borden Sales Company, Inc., New York

Description—Canned, unsweetened sterilized evaporated milk, the same as the accepted Borden's Unsweetened Evaporated Milk (THE JOURNAL, Feb. 15, 1930, p. 485)

HUBINGER CRYSTAL WHITE SYRUP

(CORN SYRUP AND GRANULATED SUGAR SYRUP)

Manufacturer—The Hubinger Company, Keokuk, Iowa

Description—Table syrup, corn syrup flavored with sucrose syrup and vanilla extract

Manufacture—Corn syrup, prepared by the usual method of acid hydrolysis of corn starch (see Penick Golden Syrup, THE JOURNAL, April 2, 1932, p. 1159), is blended with sucrose syrup and flavored with vanilla extract. The mixture is heated to 77°C and automatically packed in cans at 74°C.

Analysis (submitted by manufacturer) —

	per cent
Moisture	24.9
Ash	0.2
Fat (ether extract)	0.0
Protein (N X 6.25)	0.0
Reducing sugars as dextrose	30.9
Sucrose (copper reduction method)	8.7
Dextrins (by difference)	35.3

No methods are available for accurately determining the composition of syrups of this nature. Therefore the foregoing analysis is roughly approximate.

Calories—30 per gram, 85 per ounce

Claims of Manufacturer—For cooking, baking and table use or as a carbohydrate supplement for milk modification for infant feeding.

MCCAHAN'S SUNNY CANE SUGAR

GOLDEN YELLOW

OLD TIME BROWN

Manufacturer—The W. J. McCahan Sugar Refining and Molasses Co., Philadelphia

Description—Respectively light yellow and brown grades of refined cane sugar.

Manufacture—Syrup obtained from washing imported unrefined cane sugar crystals in the centrifugal machines (See McCahan's Sunny Cane Sugar—Extra Fine Granulated THE JOURNAL, Jan. 20 1934, p. 212) is filtered through bone black and concentrated in "vacuum" until the magma formed has the desired "grain". The crystals are centrifugated to remove excess syrup. The moist soft sugar containing varying amounts of the original syrup is cooled and graded according to the degree of color of the finished product. Darker syrups contain less sucrose and correspondingly greater amounts of invert sugar and mineral salts. Dark syrup is used to produce the "Old Time Brown" sugar and light syrup for "Golden Yellow" sugar.

Analysis (submitted by manufacturer) —

	(light)	(dark)
Moisture	per cent 4.3	per cent 4.7
Ash	0.5	1.5
Fat	Absent	Trace
Protein (N X 6.25)	0.1	0.4
Reducing sugars as invert	2.5	8.2
Sucrose (polarimetric method)	92.1	84.9

Calories—From 3.8 to 3.7 per gram from 108 to 105 per ounce

Claims of Manufacturer—These refined sugars possess a molasses-like flavor and a yellowish or brownish color, contain slight amounts of fructose (fruit sugar), dextrose (corn sugar) and mineral salts naturally found in the original cane juices.

FORESCO BRAND STERILIZED UNSWEETENED EVAPORATED MILK

Distributor—Forest City Wholesale Grocery Co., Inc., Rockford, Ill.

Packer—Dean Milk Company, Chicago

Description—Canned, unsweetened sterilized evaporated milk, the same as Dean's Quality Evaporated Milk (THE JOURNAL, Aug. 6 1932, p. 477)

FAT AND THE DIABETIC PATIENT

Conventionally, diabetes is considered a disease involving, primarily, carbohydrate metabolism. The striking effect of insulin on the concentration of blood sugar has served to confirm the association. Nevertheless, the disturbance of fat metabolism plays no small part in the pathogenesis of this disease. In a recent review Joslin¹ has summarized various aspects of the significance of fat to the diabetic patient. He repeatedly points out the great change brought about in the outlook for the diabetic child by the introduction of insulin. Among the results of the prolongation of life of this younger group of patients is the realization not only that heredity plays an important part in the predisposition to the disease but also that obesity alone is probably a less significant factor than was formerly believed, it merits special attention when there is a hereditary tendency. Although the obese person may show a decreased pancreatic efficiency, the presence of excess body fat is really a sign of overeating in general with concomitant taxing of the insular function. The rapid deposition of fat is likely to burden the pancreas to a greater extent than is a more gradual accumulation. Exercise is therefore of particular importance as a prophylactic against diabetes. On the basis of statistics as to causes of death among physicians since 1902, Joslin points out that "the doctors have profited no more from their knowledge of obesity as a cause of diabetes than the laity."

A study of the cholesterol of the blood of groups of patients with diabetes has shown a tendency to decrease in concentration during recent years from an average of 424 mg per hundred cubic centimeters of blood in 1916 to 212 mg in 1932. Similarly in the same interval there was a definite decrease in the number of clinically "severe" cases. These changes are correlated with changes in treatment which, in turn, permitted a change in the proportion of carbohydrate to fat in the diet, thus decreasing the total blood fat. Accompanying the lowered fat in the blood is a smaller incidence of coma,

one of the principal complications of diabetes. It is stated that, in general, a high blood cholesterol is reliable evidence that the diabetes is not under control, values greater than 230 mg per hundred cubic centimeters of blood should be looked on with suspicion.

With the advent of insulin, removal of all restriction on the diet has at times been urged. Joslin reviews the experience with the high fat diets during the first decade of this century, then the period when total energy intake was severely restricted but with the relative proportion of fat calories still high, and finally the modern era when the criteria for proper treatment are "health, happiness and chemical assurance in blood and urine that the disease is controlled." He prefers moderate restriction of carbohydrate with fats providing somewhat more of the total calories than usual among normal individuals but suggests that every advantage be taken of a proved increase in tolerance for carbohydrates. The current tenets of this careful student of diabetes can well be summarized by his own phrase "diet, exercise and insulin."

THE BUREAU OF MEDICAL ECONOMICS

Since the establishment of the Bureau of Medical Economics of the American Medical Association, a vast amount of data in the field of medical economics has been collected and made available to the medical profession in various forms. In fact, it is safe to say that the publications issued by this bureau, largely as a result of its own researches, are unique. The work duplicates that done elsewhere only when the bureau has repeated investigations by other agencies in order to check and confirm them.

Many of the reports have been published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and have thus been made available to physicians generally. Others, however, have been of such scope and detail that it has been found necessary to print them as separate pamphlets.¹ This has been particularly required because physicians frequently seem to overlook some of this technical material in the vast amount of scientific, editorial and journalistic material published in THE JOURNAL. In view of the importance of the Bureau of Medical Economics, it has even been suggested that these articles be printed on paper of a different color or that the items be inserted in some special part of THE JOURNAL. One physician facetiously suggested that this be among the obituary notices or the Tonics and Sedatives in order that they may be read by every physician. It is apparent that practically every doctor reads these two sections every week.

¹ The bulletins here referred to are available through the American Medical Association at the prices indicated: An Introduction to Medical Economics 15 cents, Contract Practice 10 cents, Income from Medical Practice 15 cents, Group Practice 15 cents, The Costs of Medical Education 10 cents, Collecting Medical Fees 10 cents, Medical Relationships Under Workmen's Compensation 75 cents.

The staff of the Bureau of Medical Economics has not depended for its information on data available in medical periodicals or bulletins issued by various agencies. It has not even depended largely on the questionnaire method—a method, by the way, largely followed by other research organizations and one susceptible of considerable doubt because of the psychologic factors naturally involved. During the few years since its establishment, representatives of the bureau have been in practically every state of the Union. They have studied conditions in Cuba at first hand and they are aware through direct contacts of the sociomedical situations in most foreign countries.

How many physicians realize that this bureau has now made available an "Introduction to Medical Economics," which traces the position of medical economics in relationship to economics generally, which analyzes the question of payment for medical service and the field available for the sale of such service, which considers medical care and the distribution of wealth, and which traces some of the changes in medical institutions that have occurred in recent years? The bulletins on contract practice, on the income from medical practice, on group practice and on the costs of medical education, as well as the pamphlets on prepayment plans for hospital care and on the collection of medical fees, represent studies directly related to difficult situations in the medical profession today. All sorts of hospital insurance schemes, corporation practices and similar mechanizations of medical practice have been studied in different parts of the country. The book entitled *Medical Relations Under Workmen's Compensation* is one of the most comprehensive and authoritative studies available in this field. It is more than 150 pages in scope, well organized and adequately indexed. A book on medical organization for practice in Cuba and one on compulsory health insurance schemes abroad are in process of publication.

In view of the nature and the amount of the material thus developed and made available, it is unfortunate that the vast majority of the medical profession does not take a greater interest in following the trends of medical practice. Occasionally meetings devoted to medical economics in large medical centers are largely attended, but only a few men concern themselves with committee meetings and with the details of local problems in such places. *THE JOURNAL* as a medium devoted largely to the interests of general practitioners, recognizes that many members of the medical profession may not be interested in the details of bronchoscopy, brain surgery or even the specificity of nonspecific proteins. Medical economics, however, should be the interest of every physician, particularly in these times of changing points of view and opinions swayed by propaganda. A man well informed is doubly armed against the nonmedical exploiter of medical practice and the fanatic exponents of half-baked schemes for social change.

THE HUMAN CAPILLARIES

The physician of today has become accustomed to specialization of the most specific types. Each year more specialized novelties enter the practice of medicine. Presently they become established parts of diagnostic or therapeutic routine. The x-ray laboratory and the allergy clinic represent pertinent illustrations. Among innovations in this respect is the capillary laboratory. Until lately the descriptions of the capillaries and their functions could be expressed in a few words. It sufficed to refer to them as a network of minute tubules connecting the terminations of the smallest arteries to the commencement of the smallest veins. In structure they were thought of as a single layer of elongated flattened and nucleated epithelium cells. The latter were much more difficult to observe in life than the blood cells traversing the capillaries, often in single file. The normal thickness of the walls of these vessels appears to be somewhat less than 1 micron. Little wonder that they have been described as a most essential unit of the circulatory system, the part about which least is known.

As has happened so often in other fields of study, progress in the understanding of the capillaries has been greatly promoted by the development of new methods of observation. Direct inspection as well as photography is being applied for this purpose in man as well as in experimental animals.¹ One consequence is the conclusion that somehow the capillaries are subject to changes in caliber. This has helped greatly to explain the great variations in the blood supply and consequent exchange of components between the circulating blood and its immediate environment. Hence more than a decade ago the conclusion seemed warranted that the capillary bed had the ability to respond to the local needs of the tissue by dilatation when the conditions of the tissue tend toward asphyxiation and by constriction when the local needs have been satisfied.²

How are such changes in caliber brought about? It has long been debated whether the capillaries really have the ability to contract independently or to produce peristaltic movements.³ The work of Sir Thomas Lewis and his co-workers at University College in London indicates that the capillaries and the venules are capable of active contraction. These vessels can exert a force when fully contracted which resists the full entry of blood into them up to a pressure of from 90 to 100 mm of mercury. When dilated they are able, by contracting, to expel their contents against internal pressures of at least 50 or 60 mm of mercury. This means that these vessels must be of almost as great import as the arterioles in influencing circulatory events. Wright

1 Duryee A. W. and Wright I. S. *Modern Methods for the Study of Human Capillaries*. *Am. J. M. Sc.* 5: 664 (May) 1933.

2 Hooker D. R. *Evidence of Functional Activity on the Part of the Capillaries and Venules*. *Physiol. Rev.* 1: 112 (Jan.) 1921.

3 A discussion of this and related subjects is presented in detail by Wright I. S. and Duryee A. W. *Human Capillaries in Health and in Disease*. *Arch. Int. Med.* 52: 545 (Oct.) 1933 from which many of the statements made above have been taken.

and Durvee believe that the capillary bed is responsive to chemical influences by local reactions, usually by dilatation (only in special or pathologic cases by general reactions), and to nervous stimulation usually by constriction, over the body as a whole. It is therefore likely that beyond the arterioles the capillaries and venules function actively thereby participating directly in vascular reactions. These however are views that need to be more firmly established before they can finally be classed as scientific facts.

These studies have served also to give a better understanding of capillary pressure. Although the estimation of this factor has long been the subject of experimental investigation opinions as to the values derived have varied greatly. Out of the welter of conjectures it may be tentatively concluded that the average figures for capillary pressure in man may be placed between 19 and 26 mm. of mercury. It seems possible now to allege with some conviction that the permeability of the capillary walls is subject to the laws of filtration diffusion and osmosis and is also affected by the ionic concentration at the cell membranes in the blood, the state of the endocrine system and especially the state of the visceral nervous system. In any event the time has apparently arrived for the detailed investigation of the capillaries in disease, with the expectation that the outcome will provide useful information.

CHANGES IN STATE MEDICAL PERIODICALS

The *Wisconsin Medical Journal* began 1934 with some modifications in its editorial policies. Hereafter all manuscripts read at the annual meeting of the state medical society will be considered by an editorial board with the understanding that only such papers will be published as are considered suitable by the board. Heretofore, practically all papers read at meetings of the society have been accepted. This has prevented the devotion of space to miscellaneous and volunteered contributions. The *Wisconsin Medical Journal* has also adopted a new cover without advertising and handsomely printed on an unusually fine quality of paper.

The *New York State Journal of Medicine* announces with the first issue of 1934 that it proposes henceforth to carry only clean advertising and to be free from announcements of questionable products. A new editorial board has been established. The periodical appears in a new size and with a new type face. The editorials of which there are many, are signed by individual writers and apparently were prepared especially for the *New York State Journal of Medicine*. The addition of this periodical to those which follow established standards of advertising leaves but one of the state medical journals outside the pale.

The trend toward higher standards in state medical journalism has been consistently maintained for more

than a quarter of a century. The progress here recorded is significant not only for the members of medical organizations in the states concerned but for all of American medicine. Perhaps the day may yet come when all medical periodicals, including the bulletins of county medical societies, will realize the importance of setting the highest possible ethical requirements, particularly in the advertising of foods and drugs, which come so intimately into relationship with the practice of medicine and also in the announcements of medical institutions and other accessories to medical practice.

Current Comment

AMERICAN MEDICAL ASSOCIATION BROADENS RADIO PUBLIC HEALTH EDUCATION

In cooperation with the National Broadcasting Company the American Medical Association has been for some time undertaking a considerable amount of education of the public in health by means of the radio. Under the heading "Association News" in this week's issue of *THE JOURNAL* we are privileged to present a new list of stations, forty in number, which now carry the American Medical Association broadcast every Monday afternoon from 5 to 5:15 Eastern standard time, 4 to 4:15 Central standard time, and correspondingly for Western stations. These outlets extend from Canada to the Gulf and from the Atlantic to the Pacific Ocean. The broadcasts are for the most part being made by Dr. W. W. Bauer, director of the Bureau of Health and Public Instruction of the American Medical Association, and Dr. Morris Fishbein, editor of *THE JOURNAL* and of *Hygiene*. From time to time other officers and heads of departments of the Association will explain the functions and services of the Association to the public by this medium. Such an opportunity for reaching tremendous numbers of people with dependable material in the field of medicine has never been equaled. The Association owes a debt of gratitude to the National Broadcasting Company for making these facilities available without cost and for the public good.

A DIETARY INGENUITY

The instinctive ingenuity of man in securing an adequate diet, despite the great diversity of natural food products throughout the world and the limitations that are placed on the exercise of free choice, is to scientific observers a puzzle as well as a surprising phenomenon. Somehow, in the selection of his daily regimen, man seems to "muddle through." An interesting illustration of what this may mean is afforded in some of the eating habits of the Far East. The West has become accustomed to regard milk almost as a *sine qua non* in supplying adequate amounts of calcium for human needs, at any rate the mammary secretion is *facile princeps* in the preferred sources of supply of an element that looms large in its significance for bodily well being. Among many Orientals, milk and milk products are not customarily in use yet there can be

no doubt that their diet is as a rule adequate in calories, protein and calcium. In explanation of this, many Chinese, for instance, are said to eat anything that tastes and looks good, such as butterfly wings, rose petals and shark's fins and they have a great many varieties of food in their diet even though they do not use milk or milk products. Soy beans, boiled or baked, and soy bean sprouts or soy bean curd are used extensively and are inexpensive.¹ An interesting custom in the diet of certain lactating mothers is related by a trained observer. It is considered a great honor to present to a pregnant woman a pair of pig's feet. These are chopped fine, covered with rice vinegar (made by fermenting rice), stewed ten or twelve hours, and sealed in jars. Each mother hopes to have at least twelve pairs of pig's feet prepared and set away before the baby arrives. After the baby comes, the pig's feet are served to the lactating mother four or five times a day. From recent analyses of comparable food materials it appears that considerable calcium may become available by the described culinary process. Indeed, as Frances Clinton has pointed out, it is possible that this peculiar method of cookery used extensively by the Chinese may be of particular value in providing adequate amounts of calcium.

SESQUICENTENNIAL OF THE NEW HAVEN
COUNTY MEDICAL ASSOCIATION

The history of medicine in the United States is still comparatively brief and noteworthy events are sufficiently limited in number to endow their passing anniversaries with more than indifferent significance. Only a few weeks ago there were celebrations, in many parts of the country, of the one hundredth anniversary of the publication in 1833 of Dr. William Beaumont's classic book called *Experiments and Observations on the Gastric Juice, and the Physiology of Digestion*. Before his time, as a recent writer has remarked, knowledge of the functions of the human stomach was vague and doubtful. Beaumont ushered in a new period based on his direct observations of the stomach at work. The medical profession in Connecticut, January 5, joined in the sesquicentennial of the New Haven County Medical Association. The event is of more than local interest because this association, starting in 1784, was the second to be organized in all America, the first having been the Massachusetts society of 1781. Special importance attaches to the New Haven County Association because it published the first volume of medical transactions—papers reporting cases from American medical practice. In the early days the association exercised the right to confer the degree of doctor of medicine. This prerogative was resumed for the first time in more than a century when during the sesquicentennial exercises, the degree of M.D. in honoris causa was bestowed on the dean of American physiologic chemists, Prof. Russell H. Chittenden who, as noted by the orator of the occasion, "both directly and through his pupils has influenced medical progress along chemical lines to an extent that can neither be estimated nor overestimated."

¹ These and other details have been garnered from Notes on Chinese Diets by Clinton Frances J. *Home Economics* 25: 971 (Dec.) 1933

ANNUAL CONGRESS ON MEDICAL EDUCATION, LICENSURE AND HOSPITALS

Program of Meetings to Be Held in Chicago,
February 12 and 13

The thirtieth Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held in the Palmer House, Chicago, Feb. 12 and 13, 1934. The Federation of State Medical Boards of the United States and the American Conference on Hospital Service will participate in the congress. The program follows:

MONDAY, FEBRUARY 12, 10 A. M.

RAY LYMAN WILBUR, M.D., Presiding

Review of the Accomplishments of the Council on Medical Education and Hospitals

Ray Lyman Wilbur, M.D., Chairman, Stanford University, Calif.

Philosophy of Professional Licensure

Justin Miller, J.D., Dean, Duke University School of Law, Durham, N.C.

Discussion Alphonse M. Schwaitalla, S.J., Ph.D., St. Louis

Medical Education and Its Relationship to Society as a Whole

Robert G. Sproul, LL.D., President, University of California, Berkeley

Discussion E. P. Lyon, M.D., Minneapolis

The Restoration of the General Practitioner

Dean Lewis, M.D., President, American Medical Association, Baltimore

Discussion James B. Herrick, M.D., Chicago; J. H. Musser, M.D., New Orleans

Red Lacquer Room

MONDAY, FEBRUARY 12, 2 P. M.

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE AMERICAN CONFERENCE ON HOSPITAL SERVICE

MERRITTE W. IRELAND, M.D., Presiding

Responsibility of the Hospital Trustee and the Relationship Between the Trustees and the Staff

Howard S. Cullman, President, Beekman Street Hospital, New York

Discussion Nathaniel W. Taxon, M.D., Rochester, N.Y.

Symposium: Size and Scope of a University Clinic

Henry Houghton, M.D., Director, University of Chicago Clinics

Nathan B. Van Etten, M.D., Vice-Speaker, House of Delegates

American Medical Association, New York

John H. J. Upham, M.D., Dean, Ohio State University College of Medicine, Columbus

Discussion William D. Haggard, M.D., Nashville, Tenn.; John Wickoff, M.D., New York; Austin A. Hayden, M.D., Chicago

Red Lacquer Room

TUESDAY, FEBRUARY 13, 9 A. M.

JOINT SESSION OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS AND THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES

G. M. WILLIAMSON, M.D., Presiding

The Privilege of Recrimination in Professional Licensure

Bernard C. Gavit, J.D., Dean, Indiana University School of Law, Bloomington

Discussion G. M. Williamson, M.D., Grand Forks, N.D.

Resumé of the History and Present Application of Medical Licensure in the States

J. N. Baker, M.D., Secretary, Alabama Board of Medical Examiners, Montgomery

Discussion A. T. McCormack, M.D., Louisville

Reciprocity Agreements

J. R. Neal, M.D., Secretary, Professional Committee for Medicine, Illinois Department of Registration and Education, Springfield

Discussion Harold Rypins, M.D., Albany, N.Y.

Medical Licensure in South America—Preliminary Survey

William D. Cutter, M.D., Secretary, Council on Medical Education and Hospitals, Chicago

Discussion Frederic W. Schlutz, M.D., Chicago

Red Lacquer Room

TUESDAY, FEBRUARY 13, 2 P. M.

REGINALD FITZ, M.D., Presiding

The Importance of Introducing Psychiatry into the General Internship

Franklin C. Ebaugh, M.D., Director, Division of Psychiatric Education, National Committee for Mental Hygiene, Denver

Discussion C. C. Burlingame, M.D., Hartford, Conn.

The Incorporation of the Principles of Preventive Medicine in Clinical Teaching

Wilson G. Smilie, M.D., Professor of Public Health Administration, Harvard University, Boston

Discussion C. Sidney Burwell, M.D., Nashville

The Teaching of Industrial Hygiene

I. Everett D. Bristol, M.D., Health Director, American Telephone and Telegraph Company, New York

Discussion Edward C. Holmblad, M.D., Chicago

The Function of the Physician in Public Health Education

W. W. Bauer, M.D., Director, Bureau of Health and Public Instruction, American Medical Association, Chicago

Discussion H. S. Cumming, M.D., Washington, D.C.

Red Lacquer Room

TUESDAY, FEBRUARY 13, 2 P. M.

THE FEDERATION OF STATE MEDICAL BOARDS OF THE UNITED STATES
G. M. WILLIAMSON, M.D., Presiding*Traffic in Narcotics by Licensed Physicians*

H. J. Anslinger, United States Commissioner of Narcotics, Washington, D. C.

Discussion W. L. Treadway, M.D., Washington, D. C.*The Use of the Injunction Procedure in Enforcing Medical Practice Acts*
F. Manley Brist, II, B. Attorney, Minnesota Board of Medical Examiners, St. Paul*Discussion* H. M. Platter, M.D., Columbus, Ohio

Room 14

Federation Dinner Monday, 6:30, Palmer House. The Federation of State Medical Boards of the United States. Address: Relation of Education to Licensure, Walter A. Jessup, Ph.D., President, State University of Iowa, Iowa City. Presidential Address of G. M. Williamson, M.D., Informal round table discussion.*Evening Meeting* Monday, 8:15, Red Lacquer Room, Palmer House. American Conference on Hospital Service. Address: The Old and the New in Medicine, Dean Lewis, M.D., President, American Medical Association, Baltimore.*Luncheon* Tuesday, 12:30, Grand Ball Room, Palmer House. Central Council for Nursing Education. Address: What Is the Future of Nursing? Hugh Cabot, M.D., Professor of Surgery, University of Minnesota Graduate School of Medicine, Minneapolis.

MEDICAL BROADCAST FOR THE WEEK

Talks over Network of the National
Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15, central standard time (5 o'clock, Eastern standard time, 3 o'clock Mountain standard time, and 2 o'clock, Pacific standard time). The subject for Monday, January 29, is Warm Water Healing. The speaker will be Dr. W. W. Bauer, director, Bureau of Health and Public Instruction of the American Medical Association. The program is now being broadcast by the following stations:

New England States	South Atlantic States
WBZ Boston	WBAL Baltimore
WBZA Springfield, Mass.	WMAI Washington
Middle Atlantic States	WJAX Jacksonville
WJZ New York	WIOD Miami
WSR Syracuse	WTIA Tampa
WHAM Rochester	WSB Atlanta
KDKA Pittsburgh	East South Central States
East North Central States	WSM Nashville
WGAR Cleveland	WMC Memphis
WCKY Cincinnati	WJDX Jackson, Miss.
WENR Chicago	West South Central States
WJR Detroit	WSMB New Orleans
WIBA Madison, Wis.	KVOO Tulsa
West North Central States	WFAA Dallas
KSTP St. Paul	KPRC Houston
WEBC Duluth	KTBS Shreveport
WDAY Fargo	KTIS Hot Springs
KFYR Bismarck	WOAI San Antonio
KOIL Omaha	Mountain States
KWCR Cedar Rapids, Iowa	KOA Denver
WREN Kansas City, Mo.	KDYL Salt Lake City
Pacific States	
KGO San Francisco	
KFI Los Angeles	
KHQ Spokane	
KFSD San Diego	

Radio Talks from Station WBBM

The American Medical Association broadcasts on Tuesday and Thursday mornings from 8:55 to 9 o'clock, central standard time, over Station WBBM (770 kilocycles, or 389.4 meters).

The subjects for the week are as follows:

January 30 New Findings in Oral Hygiene
February 1 The Health Examination

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 8:55 to 9:10 over Station WBBM.

The subject for the week is as follows:

February 3 Medicine and Superstition

THE CLEVELAND SESSION
Demonstrations on Fresh Pathology in the
Scientific Exhibit

The special exhibit on fresh pathology will be shown again in the Scientific Exhibit at the Cleveland Session, June 11-13. Dr. B. S. Kline of Cleveland will be in charge of the exhibit and will be assisted by leading pathologists, who will give practical talks and personal demonstrations continuously throughout the week.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Outbreak of Spinal Meningitis—Six deaths were reported in a recent outbreak of spinal meningitis at the Tucker Prison Farm. It was reported January 5. At that time the camp were placed under quarantine and local health officials had requested federal authorities for assistance in curbing the outbreak. Plans were going forward to examine every person at the prison farm, including officials, to determine whether the disease was being transmitted by a carrier.**New Medical School Building**—Funds totaling \$500,000, provided through a loan and a grant by the Public Works Administration, make possible the construction of a new building at the University of Arkansas School of Medicine, Little Rock, newspapers announce. The building will be erected on a site facing the city park, and it is expected to be ready for opening next fall. The building will be five stories high and offer accommodations for 300 students. It will house all departments of the medical school. Under present arrangements the first two years work has been conducted at the War Memorial Building and the last two at various hospitals. Construction of a new building was authorized by the legislature in 1931 through the sale of bonds but was never carried out. Plans for the building were completed eighteen months ago.

COLORADO

Society News—At a meeting of the Crowley County Medical Society in Ordway, December 14, Drs. George B. W. Baker, Rocky Ford, and William S. Bartholomew, Manzanola, discussed Huntington's disease and normal digestion, respectively. A symposium on cancer was presented before the Fremont County Medical Society, December 18, at Florence by Drs. George W. Bancroft, Colorado Springs, and Josephine N. Dunlop and George A. Unfug of Pueblo. Dr. John E. Ford, Grand Junction, spoke on epilepsy before the Mesa County Medical Society, November 21. At a meeting of the North Creek Colorado Medical Society in Sterling, December 14, Dr. Kemp G. Cooper, Denver, gave a lantern slide presentation of 'Intestinal Obstruction and Tumors of the Sinuses.'

CONNECTICUT

Personal—Dr. George T. Pack, New York, has been appointed assistant clinical professor of surgery at Yale University School of Medicine, New Haven, on a part time basis.—Dr. Stanley Harcourt Peppard, formerly director, bureau of mental hygiene, Connecticut State Health Department, has been appointed medical director at "Blythewood" Greenwich.—Dr. Israel S. Otis recently submitted his resignation as city physician of Meriden.—Dr. Alphonse Fontaine has been appointed health officer of the borough of Danielson.—Dr. Ettore F. Carniglia has been named health officer of Windsor Locks, succeeding the late Dr. Joseph A. Coogan.

ILLINOIS

Personal—Dr. Wilnot L. Ransom, Rockford, was made an honorary member of the Winnebago County Medical Society at its meeting January 9. Dr. Ransom has practiced in the county for sixty years.—Dr. John G. Young has been named physician for the state reformatory at Pontiac, succeeding Dr. James A. Marshall.—Dr. Robert C. Hitchings, Donovan, was guest of honor at a banquet November 26 on the occa-

sion of his sixty-seventh birthday —Dr Robert R Smith, Mount Vernon, has been appointed managing officer of the Kankakee State Hospital

Chicago

Study of Maternal and Fetal Mortality —The Chicago Gynecological Society recently organized a maternal welfare committee to make a study of maternal and fetal mortality in Chicago. The obstetric mortality and morbidity of mothers and babies will be considered with a view to studying controllable factors

Society News —Dr Otto H Schwarz, St Louis, addressed the Chicago Gynecological Society, January 19, on 'Treatment of the Late Toxemias of Pregnancy'. —The Chicago Society of Allergy was addressed, January 15, by Dr Ludvig Hektoen and William H Welker, PhD on 'Methods of Immunization' and 'Autogenicity of Proteins,' respectively. —Dr Roderic P O'Connor, San Francisco, spoke before the Chicago Ophthalmological Society, January 15 on 'Cataract Extraction by the Undetached Conjunctival Bridge Method After Preliminary Iridectomy'. —At a meeting of the Chicago Neurological Society, January 18 the speakers included Ralph W Barris on 'Optic Connections of Midbrain and Thalamus'. —Dr Kamil Schullhof addressed the McDonagh Society for Clinical Research January 19, on 'Significance of Electric Charges for the Transport of Substances in the Tissues'. —Speakers before the Chicago Orthopedic Club, January 19 were Drs Peter A Bendixen, Davenport Iowa on 'Fractures of the Elbow,' and Claud R G Forrester, Reduction of Fractures Under Local Anesthesia Together with Ambulatory Treatment'. —Among others Dr Jerome R Head discussed 'Clinical Observations on the Intrapleural Pressure' before the Chicago Society of Internal Medicine, January 22

INDIANA

Portrait of Dr Henry —Memorial services in honor of the late Dr Alfred Henry in the Indianapolis City Hospital December 12, marked the first anniversary of his death. His portrait was presented to the tuberculosis clinic of the hospital by the Marion County Tuberculosis Association, of which he was at one time president. Dr Edward M Amos, president of the association, made the presentation to Dr Charles W Myers, superintendent of the hospital. Among other offices he held Dr Henry served as president of the National Tuberculosis Association and the Mississippi Valley Conference on Tuberculosis

Immunization Campaign —The plan to immunize every child in the state against diphtheria and smallpox has been placed in operation. However, no child will be immunized whose parents do not specifically request it. Material for the immunization of 75,000 children was provided through funds made available in the state division of public health. Children of parents unable to pay will be given treatments without charge by family physicians, who will procure their materials free from the state division of public health. It is expected that the costs of immunizing materials for the indigent children of the state will not exceed \$15,000. The program was initiated by the Indiana Advisory Public Health Council, which includes representatives of medical and lay organizations interested in child welfare

Session on Maternal Health —A program on maternal health was presented before the Carroll County Medical Society in Delphi December 8, by the department of obstetrics of Indiana University School of Medicine and the state board of health. In the afternoon, clinics were conducted by Drs Arthur M Mendenhall on the thyroid and pregnancy, John F Kelly, toxemias of pregnancy, and Arthur J Micheli edema and varicosities. Addresses were given by Dr Mendenhall, on hemorrhages in obstetrics, Micheli, on prenatal care in general practice, and Kelly, on home obstetrics. Dr James W Jackson of the state board of health also spoke. An evening session for both physicians and laymen was addressed by Drs Mendenhall on importance of obstetrics, and Ernest O Asher, better obstetrics

Society News —Dr Richard H Miller, Boston, spoke before the Indianapolis Medical Society, January 16 on 'Ulcer and Cancer of the Stomach'. —The Grant County Medical Society was addressed in Marion, December 27 by Dr Charles P Emerson, Indianapolis, on 'Medicine in the Orient'. —At a meeting of the Hancock County Medical Society in Greenfield December 11, it was decided to admit dentists to membership on their payment of the dues of \$1. With the admission of two new members the society now has a 100 per cent mem-

bership of physicians of the county. Speakers were Paul A Allen and Dr Edgar A Hawk, New Palestine, on 'Dental Practice During Pregnancy' and 'Cesarean Section and Its Sequelae,' respectively. —Dr Stanley Milton Goldhamer, Ann Arbor, Mich. addressed the Northeastern Indiana Academy of Medicine in Kendallville, December 21, on pernicious anemia

KANSAS

Society News —The Anderson County Medical Society was addressed, November 15, by Dr James R Nevitt, Kincaid, on undulant fever. Dr Louie F Barney, Kansas City, spoke before the society December 27, on 'Medicine, Past and Present'. —The Washington County Medical Association was recently organized with Dr Fred H Rhoades, Hanover, as president

KENTUCKY

Bill Introduced —H 13, to amend the workmen's compensation act, proposes to make compensable 'injuries or death due to the inhalation of any kind of gas and the inhalation of silica dust'

Health Commissioners Appointed —Dr Hugh Rodman Leavell has been named health commissioner of Louisville and Dr John D Trawick of Jefferson County. They plan to coordinate the city and county services to avoid duplication, it was announced. Dr Trawick has practiced in Louisville for many years but will not continue private practice during his term as health officer. Dr Leavell is a native of Louisville and a graduate of Harvard University Medical School, class of 1926. He has been in charge of the student health center of the University of Louisville for several years

MASSACHUSETTS

Dr Mallory Honored —A special issue of the *American Journal of Pathology* has been dedicated to Dr Frank Burr Mallory, since 1928 professor of pathology, Harvard Medical School Boston, in commemoration of his seventieth birthday and of the opening of the Mallory Institute of Pathology of the Boston City Hospital. Graduating from Harvard in 1890 Dr Mallory became associated with the medical school in 1891. Since then he has held several teaching positions, becoming professor of pathology in 1928. He had been pathologist to the hospital since 1908. He retired from these positions last year when he reached his seventieth birthday, becoming consulting pathologist to the hospital. A member of several societies Dr Mallory was made editor-in-chief of the *Journal of Medical Research* in 1923 continuing in that capacity when its name was changed, in 1925, to the *American Journal of Pathology*. At a dinner in his honor, December 13, speeches were made by Mr F C Hood representing Dr Mallory's class at Harvard College, Dr Elliott C Cutler, representing the surgical profession, Dr Hans Zinsser, representing bacteriologists, and Dr James Ewing New York, representing pathologists. Dr Simeon Burt Wolbach was toastmaster. Dr Mallory was presented with a complete moving picture outfit and a silver pitcher as tokens of the esteem of his former pupils and his friends on the occasion of his retirement and the dedication of the building

Bills Introduced —S 63 proposes that any physician selected by an employee injured in the course of his employment or by any person injured as the result of the operation of a motor vehicle shall be paid directly, respectively, by the insurer of the employer or by the insurer of the person whose motor vehicle caused the injury. H 192 proposes to prohibit physicians from dispensing prescriptions 'except in an emergency at the bedside, under the same conditions as pertain to the administration of narcotics, and in towns and villages in which there is no store with a registered pharmacist in attendance'. H 393 to supplement the dental practice act, proposes to provide the following grounds for which a license may be revoked: (1) conviction of a crime involving moral turpitude, (2) incompetence to continue practice because of persistent inebriety or addiction to drugs, (3) affliction with one or more of the 'specific' infections, (4) dishonorable or grossly unprofessional conduct, or (5) the use of fraudulent or misleading advertisements. H 509, to amend the medical practice act, proposes that 'the practice of medicine shall include the administering to human beings of ether, chloroform, nitrous oxide gas or other substance or gas producing unconsciousness except when administered by a registered dentist'. H 511 proposes to establish a board of registration of hairdressers and to regulate the occupation of hairdressing. Licentiatees are to be prohibited from removing 'superfluous hair or skin blemishes by direct application of an electric current'

MICHIGAN

Personal—Dr William C Huyser Kalamazoo was elected president of the Kalamazoo Academy of Medicine December 19.—Dr Edwin R VanderSlice has been appointed health officer of Lansing, succeeding the late Dr S Rowland Hill

To Study European Health Insurance—Nathan Sinar, Dr P H, professor of public health, University of Michigan School of Medicine Ann Arbor and Dr Henry A Luce, Detroit, past president of the Wayne County Medical Society, recently sailed for Europe to make a study of health insurance plans, newspapers report. The Michigan State Medical Society is sponsoring this trip as a part of its survey of health insurance

MINNESOTA

Anniversary Dinner—Dr Lester R Dragstedt professor of surgery University of Chicago, will be the guest speaker at the twelfth annual anniversary dinner of the Minneapolis Surgical Society at the Minneapolis Club February 1. His subject will be "The Etiology of Gastric Ulcer"

"Medical Service Company" to Be Dissolved—The attorney general of the state December 2, instituted quo warranto proceedings against the Medical Service Company, a Minnesota corporation which had been shown to be practicing medicine. The object of the proceedings was to have the corporate charter of the Medical Service Company forfeited to the state and to restrain the corporation from practicing medicine. The corporation agreed, however, to suspend activities and to surrender its charter on or before February 20

Dr Lewis to Give the First Judd Lecture—Dr Dean Lewis, President, American Medical Association and professor of surgery, Johns Hopkins University School of Medicine, Baltimore, will deliver the first Judd lecture at the University of Minnesota, February 13, on "The Hypophysis, the Master Gland. The History, Physiology, and the Clinical Symptoms Associated with Its Lesions". This lectureship in surgery, to be given annually, was endowed by Dr Edward Starr Judd, professor of surgery in the Mayo Foundation, Rochester, and a former president of the American Medical Association

Parrakeets Barred from State—A resolution was adopted by the Minnesota State Board of Health at a recent special meeting, prohibiting the shipment of parrakeets into the state until such time as it can be demonstrated that the varieties from which they are shipped are free from infection. The resolution refers to the appearance of psittacosis in other states which have been traced to infected varieties in California. Since it is practically impossible to exclude carriers of the infection from infected areas and because infected birds are continually reported to be coming from California and foreign ports, the board feels that the ban is necessary

MISSISSIPPI

Bill Passed—H 95 has passed the House, proposing to amend the law forbidding the sale, barter or giving away of commodities intended for smoking, containing cannabis indica so as to forbid also the keeping or possessing of such commodities

Bills Introduced—S 108 proposes that the South Mississippi Charity Hospital, the Matty Hersee Hospital, the Jackson Charity Hospital, the Vicksburg Charity Hospital and the Natchez Charity Hospital be abolished as public charity hospitals and that the boards of trustees of those hospitals be authorized to dispose of all of the real and personal property of those hospitals. H 155, to amend the pharmacy practice act, proposes, among other things, that (1) the provisions of the act shall not be held to prevent physicians from compounding their own prescriptions, instead of exempting physicians from the provisions of the act, as the present act does and (2) applicants for licensure as registered pharmacists must be graduates of recognized schools of pharmacy and, in addition must have had one year of practical experience in a drug store where physicians' prescriptions are compounded

MISSOURI

Meeting in Honor of Dr Starkloff—The St Louis Medical Society will offer its program, January 30 in appreciation of the years of service of Dr Max Starkloff formerly health commissioner of St Louis. Speakers will include Dr Elsworth S Smith who will review Dr Starkloff's career and Dr Arthur T McCormack, state health officer of Kentucky

"Medical School" Discontinued—The Bulletin of the Kansas City University of Physicians and Surgeons Vol 22

No 1, January, 1934 announces that in September 1933 the Kansas City University of Physicians and Surgeons was returned to the original management of the Central College of Osteopathy, also that "it is now deemed advisable to discontinue the Medical school and operate only Central College offering a complete course of study embodying all the courses of modern Osteopathy". The degree of doctor of medicine will not be conferred

Dr Elschning Conducts Course in Ophthalmology—Dr Anton Elschning, professor and head of the department German University Eye Clinic, Prague, Czechoslovakia will give a course in ophthalmology in St Louis, February 13-17 under the auspices of the ophthalmic section of the St Louis Medical Society and the St Louis Ophthalmic Society. Lectures will begin at 3:30 p m, except on Saturday, when there will be an operative demonstration from 2 to 5 p m. The fee is \$15. Registration may be made with Dr Lawrence T Post, McMillan Hospital 517 South Euclid Avenue, St Louis

NEW YORK

Bill Introduced—S 103 proposes to create a board of barber examiners and to regulate the practice of barbering

Society News—Speakers before the Onondaga County Medical Society, Syracuse January 2, were Drs Catherine M Knowlton who reported a clinical and experimental study of serum sickness and Drs Orren D Chapman and Joseph R Wiseman who presented papers on "Hypersensitiveness in Animals and Man" and "Clinical Interpretation of Allergic Conditions" respectively. Dr Edward M Livingston, New York, addressed the society, December 5, on "Abnormalities of the Superficial Veins as an Aid to Abdominal Diagnosis". Dr James Alexander Miller, New York addressed the Medical Society of the County of Westchester, White Plains January 16 on "Diseases of the Lungs Following Upper Respiratory Infections". The exhibit of the American Society for the Control of Cancer which was shown at the Century of Progress Exposition in Chicago in 1933 was shown at this meeting

New York City

Hospital News—Dr I Newton Kugelmass delivered an afternoon lecture at the New York Polyclinic Medical School and Hospital December 19 on "Hemorrhagic Diseases in Infancy and Childhood".—Dr Arthur A Landsman delivered a lecture on "Horseshoe Fistula" at the Jewish Memorial Hospital, January 9

The Salmon Lectures—Dr Charles Macfie Campbell professor of psychiatry, Harvard University Medical School Boston will deliver the Thomas W Salmon Memorial Lectures for 1934. His subject will be "Trends in Psychiatry" and the dates April 13, 20 and 27. Dr Campbell is also director of the Boston Psychopathic Hospital and is a former president of the Massachusetts Society for Mental Hygiene. The Salmon Fund was established in January 1931 as a memorial to the late Dr Salmon, who died suddenly, Aug 13, 1927. In addition to the annual lectures, the fund provides grants for financial assistance to research projects. It is administered by the New York Academy of Medicine

Committee Charges Abuse of Hospital Charity—A committee of the Bronx County Medical Society, headed by Dr Nathan B Van Etten, announced, January 13, the results of an investigation of the financial condition of 1,000 charity patients of Morrisania City Hospital. Cases were classified as follows: 583 were unable to pay, 118 were able to pay without question, 107 were able to pay with help from parents or relatives, 85 gave false addresses, 107 could possibly have paid a physician, obtained credit or paid minimum rates at a semi-private institution. Among the "charity patients" were found many "city employees, some drawing large salaries, and members of their families, receiving free treatment and free operations," the report said. As the cost to the city for patients is \$4.12 per day and each patient stays an average of eleven days in the hospital, it was estimated that if 10 per cent of the 16,000 patients cared for at Morrisania were able to pay, the city was defrauded of \$72,512. The same rate for the three general hospitals in the Bronx would bring the loss to more than \$200,000. Adding those in the doubtful classes, the committee estimated the total loss at about \$600,000. The report recommended the establishment of a credit agency in every city hospital to determine the financial responsibility of all applicants and a central bureau to coordinate all the agencies. Dr Van Etten is medical director of Morrisania Hospital

OHIO

State Society in New Quarters—The Ohio State Medical Association has moved into new offices in the Hartman Building, 79 East State Street Columbus

Society News—Drs William B Morrison and Roy I Krigbaum addressed the Columbus Academy of Medicine December 11, on progress in surgery and obstetrics respectively—Dr Arthur G Davis, Erie Pa addressed the Ashland County Medical Society Committee on Treatment of Fractures of the Vertebrae and Various Open Reduction Operations Involving the Humerus Tibia and Hip—Dr Myron Metzenbaum Cleveland addressed the Dayton Otolaryngological and Ophthalmological Society December 12 on "Reconstructive Surgery of the Eyelids Cleft Palate and Nasal Surgery"—The Union Medical Association of the Sixth Council District met, January 10 at Massillon State Hospital, Massillon Among the speakers were Drs Arthur C Gillam of the hospital staff, on "Hallucinations and Diaphoresis", John D O'Brien Canton, Treatment of Neurosyphilis and Arthur G Hyde, superintendent of the hospital "Nine Years Experience with Malaria in the Treatment of General Paralysis" Dr Clyde L Cummer, Cleveland president of the state medical association also made an address—Dr George M Curtis, Columbus, addressed the Cincinnati Academy of Medicine, January 8, on "Iodine Metabolism in Toxic Goiter" and Dr John A Kolmer Philadelphia, January 15, on "Criteria for Evaluating Compounds Employed in the Treatment of Syphilis and the Amount of Treatment to Be Given"—Dr Norman F Miller Ann Arbor Mich addressed the Academy of Medicine of Toledo and Lucas County December 1 on pelvic infections

PENNSYLVANIA

Personal—Dr Ray P Moyer has been appointed health officer of Pittsburgh succeeding Dr William W McFarland—Dr Fred W Heyer Nanticoke has been appointed chief surgeon at the Nanticoke State Hospital to succeed his brother the late Dr Edward G Heyer

Society News—Speakers at the meeting of the Allegheny County Medical Society, Pittsburgh, January 16 were Drs Harry Leonard Baer, on tularemia George J Wright pernicious anemia, with special consideration of neurologic aspects and Edwin P Buchanan, carcinoma of the breast The Pittsburgh Medical Center presented a scientific exhibit

Philadelphia

Personal—Dr Pascal F Lucchesi has been appointed superintendent of the Philadelphia Hospital for Contagious Diseases he has been acting in this capacity since the death of Dr Samuel S Woody Dec 28 1931—Dr Thomas A Shallow, professor of surgery Jefferson Medical College has been named a member of the Board of City Trusts

Society News—The Philadelphia County Medical Society devoted its meeting January 17 to Diabetes—the Problem of the Practicing Physician Speakers were Drs Howard W Schaffer on diagnosis and laboratory control Joseph T Beardwood Jr standardization of diabetic patients with diet and insulin Reuben Davis Jr prevention and control of common complications and Edward S Dillon diabetes as a public health problem

RHODE ISLAND

Bill Introduced—H 521 proposes to make it a misdemeanor for any authorized officer or investigator to interrogate any person injured in an accident as to the cause or nature of the accident or injury until the injured person has received first aid or other necessary treatment

VIRGINIA

Dr Leigh Honored—The Norfolk County Medical Society recently conferred on Dr Southgate Leigh Norfolk the title of honorary member Dr Leigh is a former president of the county society and also of the Medical Society of Virginia the Seaboard Medical Association the Tri-State Medical Association and various special societies In 1929 he was awarded the Norfolk Distinguished Service Medal in recognition of his interest in the city's welfare Dr Leigh has also been a member of the House of Delegates of the American Medical Association for a number of years

Society News—Dr Richard W Garnett Danville among others addressed the South Piedmont Medical Society at a meeting in Danville November 28 on eugenics and birth control—Drs John Lewis Rawls Suffolk and Frank I Steele

Windsor were speakers before the Second District Medical Society at Smithfield November 22, on hematuria and undulant fever respectively—Drs William H Toulson, Baltimore and Kenneth F Macey University, addressed the Medical Society of Northern Virginia at Front Royal, November 20 on Kidney Infections and "Undulant Fever in Virginia" respectively—Dr William W S Butler, Jr addressed the Roanoke Academy of Medicine October 2, on "Roentgen-Ray Aids in Management of Prostatic Enlargement"—Dr Robert V Funsten University, addressed the Rockingham County Medical Society Harrisonburg December 12, on Fractures About the Shoulder and Hip—Sidney S Negus Ph D Richmond among others addressed the quarterly meeting of the Southside Virginia Medical Association at Petersburg December 12 on the new federal Food and Drugs Act

WISCONSIN

Graduate Lectures in Physiology—Eight lectures in physiology will be presented at Marquette University Medical School during February and March by the educational committee of the Medical Society of Milwaukee County Speakers and subjects will be

February 5 Dr Raphael Isaac Ann Arbor Mich Physiology of the Blood
February 12 Walter J Meek Ph D Madison Physiology of Circulation
February 19 Dr John A F Foster Madison Cardiac Output in Health and Disease
February 26 Raymond C Herrin Ph D Madison Physiology of Respiration
March 3 Dr Walter C Alvarez Rochester Minn Anatomy and Physiology of the Gastrointestinal Tract and the Liver
March 12 Dr Andrew C Ivy Chicago The Sympathetic Nervous System
March 19 Dr Arno B Luckhardt Chicago Endocrinology
March 26 Dr Harry A Beckman Milwaukee Water Balance

GENERAL

Health Agencies Move—The National Tuberculosis Association announces its removal, along with other members of the National Health Council, from 450 Seventh Avenue to 50 West Fiftieth Street, New York

Meeting of Bacteriologists—Dr Milton J Rosenau, Boston, was elected president of the Society of American Bacteriologists at the annual session in Philadelphia December 28 Karl F Meyer, Ph D, San Francisco was named vice president and James M Sherman, Ph D Ithaca N Y reelected secretary Dr Ludvig Hektoen retired head of the department of pathology Division of Biological Sciences University of Chicago was elected an honorary member said to be the first so chosen since 1917

Change of Status in Licensure—The California State Board of Medical Examiners has reported the following

Dr Louis A Trury Los Gatos placed on probation for five years during which time he shall not apply for or possess a narcotic permit or have narcotics in his possession

Dr James A Hadley Arcata license revoked October 19 for narcotic violation

Dr Matthew J Marmillion Los Angeles license revoked October 19 for alleged illegal operation now serving a sentence of from ten years to life in San Quentin Prison

Dr Roy F Ruth Los Angeles license revoked October 19 for narcotic conviction

Dr Daniel B van Wagenen Ocean Beach license revoked October 19 for alleged illegal operation

Dr Isidor A Wallach Los Angeles placed on probation for five years having been found guilty of aiding and abetting two so-called beauty specialists October 19

Dr Clayton E Wheeler San Francisco placed on probation for five years with certain restrictions for alleged deceptive advertising

Dr Clark S Smith Oakland license restored October 16 and placed on five years probation without narcotic privileges

Dr Joseph T Wrenn San Francisco license restored October 16 and placed on five years probation

Dr Simon R Zacharich San Francisco license restored October 16 and placed on five years probation without narcotic privileges

The Department of Health of West Virginia reports

The license of Dr Elmer Groves Kesler Williamsburg revoked in March 1932 was restored November 17

The New York State Board of Medical Examiners reports the following action taken November 23

License of Dr Samuel H Kauffman Rochester revoked following his conviction of grand larceny he is serving a sentence in Auburn prison

Society News—The American Association for the Study and Control of Rheumatic Diseases will convene in Cleveland June 11 Dr Ernest E Irons Chicago is president of the association which was organized in Milwaukee in June 1933 It is an outgrowth of the American Committee for the Control of Rheumatism which continues to function as its advisory council—Dr Frank D Dickson Kansas City was chosen president-elect of the American Academy of Orthopedic Surgeons at its annual meeting in Chicago January 8-10 and

Dr. Philip D. Wilson, Boston, was installed as president. Other officers of the academy are Drs. Ernest W. Clark, San Francisco, vice president, Eugene Bishop Mumford, Indianapolis, treasurer, and Philip Lewin, Chicago, secretary. The third annual meeting of the academy will be held in New York, Jan. 14-16, 1935.—At a recent meeting in Philadelphia of the board of governors of the Association of Physicians' Square Clubs of America, consisting of Masonic physicians, a program was adopted. Masonic physicians who are interested are advised to write to the committee chairman, Dr. Joseph B. Wolff, 1829 Pine Street, Philadelphia.

Medical Bills in Congress—Hearings. The House Committee on the Judiciary held hearings January 19 on H. R. 5978, a bill proposing to liberalize existing law relative to the dissemination of information relating to the prevention of conception and articles, instruments, substances, drugs and medicines designed adapted or intended for the prevention of conception. **Bills Introduced.** S. 2101 introduced by Senator Hayden, Arizona, proposes to prohibit the sending of unsolicited merchandise through the mails. S. 2119, introduced by Senator George, Georgia, provides for the further development of vocational education in the several states and territories. S. 2115 introduced by Senator Reed, Pennsylvania, proposes to provide additional benefits for veterans. Among other benefits it provides that any World War veteran employed in the active military or naval service between April 6, 1917 and Nov. 11, 1918 in need of hospitalization or domiciliary care who is unable to defray the necessary expenses therefor is to be furnished such necessary hospitalization or domiciliary care in any Veterans Administration facility irrespective of whether the disease, disability or defect was due to service. A statement by the veteran that he is unable to defray the necessary expenses must be accepted by the Administrator of Veterans Affairs as sufficient evidence of that fact. The following bills provide benefits for veterans similar to the benefits provided by S. 2115, the bill just discussed: S. 2120 and S. 2374 introduced by Senator George, Georgia; H. R. 6193 introduced by Representative Kelly, Pennsylvania; H. R. 6543 introduced by Representative Maloney, Connecticut; H. R. 6547 introduced by Representative Carter, Wyoming; H. R. 6608 introduced by Representative Edmonds, Pennsylvania; H. R. 6665 introduced by Representative Cartwright, Oklahoma; H. R. 6666, introduced by Representative McFarlane, Texas; H. R. 6667, introduced by Representative Marland, Oklahoma; H. R. 6668 introduced by Representative Cochran, Pennsylvania, and H. R. 6671 introduced by Representative Hickenloper, Oklahoma. S. 2121, introduced by Senator George (by request), Georgia, and H. R. 6150 introduced by Representative Rankin (by request), Mississippi, propose to repeal all public laws granting medical or hospital treatment, domiciliary care, pensions and other benefits to veterans and their dependents, for injury or disease incurred or aggravated in line of duty in the military or naval service and to reenact certain sections of the World War Veterans Act, 1924, as amended relating to the granting of compensation and other allowances, and medical or hospital treatment for service-connected disability or death. S. 2355, introduced by Senator Stephens (by request), Mississippi, proposes to prevent the manufacture, sale or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines, cosmetics and liquors, and for regulating traffic therein. The foregoing bill is similar to H. R. 6376, introduced by Representative Black, New York; H. R. 6555 introduced by Representative McSwain (by request), South Carolina, provides that for the purpose of promotion, longevity pay and retirement there shall be credited to officers of the Medical Corps all active service as officers of the Medical Reserve Corps rendered by them between April 23, 1908, and April 6, 1917.

FOREIGN

General Conference of Chinese Medical Association.—The second general conference of the Chinese Medical Association will be held in Nanking, March 31-April 7. Complete information may be had from Dr. H. P. Chu, general secretary, Chinese Medical Association, 41 Tzepang Road, Shanghai.

International Radiologic Congress in Switzerland.—The fourth International Congress of Radiology will be held in Zurich, July 24-31, 1934. The program of the general meetings includes addresses on radiation treatment of various types of cancer, mitogenetic radiation, radiation genetics, short wave therapy, measurement of the dosage in x-ray and radium treatment, structure analysis and physical aspects of x-rays. Among American radiologists listed on the program are Drs. Joseph C. Bloodgood, Baltimore, Henry Schmitz, Chicago, George

E. Pfahler, Philadelphia, Douglas Quick, New York, Hermann J. Muller, Ph.D., Austin, Texas, and Giacomino Failla, Ph.D., and Edith Qumby, both of New York. Dr. Hans P. Schmitz is president of the congress and Dr. Hans E. Walther, Zurich, Gloriarstrasse 14, is secretary.

Government Services

Annual Report of the Veterans' Administration

The Administrator of Veterans Affairs, Frank T. Hines, submitted to the Congress of the United States, January 3, the Annual Report of the Veterans Administration for the fiscal year ended June 30, 1933. The hospital load of the Veterans Administration on that date was 33,790, a decrease of 10,046 or about 23 per cent in the number on the last day of the previous fiscal year. Of the total load, 16,290 were World War veterans receiving treatment for disability not the result of service; 2,787 were veterans of wars prior to the World War, and 201 were employees of the Civilian Conservation Corps. Sixteen per cent of the patients then present in hospitals had tuberculosis, 60 per cent neuropsychiatric diseases and 24 per cent general medical and surgical conditions. This is a marked change since June 1923 when 41 per cent of the veterans were under treatment for tuberculosis, 39 per cent for neuropsychiatric diseases and 20 per cent for general conditions.

Since March 3, 1919, there have been 1,277,624 admissions to hospitals, of which 136,626 were made during the last fiscal year. Since June 7, 1924, when hospitalization was first authorized for the veterans of all wars without regard to the origin of their disabilities, 531,715 or 62 per cent of all admissions had been for the treatment of non service-connected disabilities. About three fourths of the admissions in the last fiscal year were for non service-connected disabilities. During this year 71,139 or 52.07 per cent of the total were first admissions while 62,112 or 45.46 per cent were readmissions.

About 179,400 patients were under hospitalization during the year of whom 145,937 were discharged after an average of 96.5 inpatient days. 86 per cent of these remained until the completion of the hospitalization episode. During the year 7,375 patients died in hospitals and 60 per cent were among patients under treatment for general diseases, 28 per cent for pulmonary tuberculosis and 12 per cent for neuropsychiatric diseases. Eleven per cent of the pulmonary tuberculosis cases resulted in death, 4 per cent of the general and 2 per cent of the neuropsychiatric. This decrease was the direct result of the act of Congress approved March 20, 1933, which denied the benefit of hospitalization to many veterans who had been eligible under prior laws. This law also resulted in a decrease of 8 per cent in the number of admissions to hospitals over the number admitted in the previous fiscal year.

The Veterans Administration was operating June 30, 1933, hospital facilities at seventy-one locations in forty-three states and the District of Columbia, providing a total of 40,213 beds, or an increase of 3,641 beds over those available at the end of the previous year, practically all of which increase was for the care of psychotic and general medical and surgical patients. Seven newly constructed hospitals were opened during the year: March, at Tusculoosa, Ala.; Albuquerque, N. M.; Curandigua, N. Y.; Columbia, S. C.; Salt Lake City, Utah; Huntington, W. Va.; and St. Petersburg, Fla. Additional hospital beds were acquired through new construction or alterations at a number of other locations. Three new facilities were completed this year but were not opened: namely, at Wichita, Kan. (162 beds), Cheyenne, Wyo. (108 beds), and Roseburg, Ore. (191 hospital and 350 barrack beds). During the year three facilities were closed: namely, at Philadelphia (416 beds), Kansas City, Mo. (200 beds), and Dwight III (225 beds). With the closing at Kansas City, all facilities controlled by the Veterans Administration are government owned. The Congress of the United States has appropriated since February, 1919, the sum of \$119,952,000 for new hospitals, domiciliary and outpatient dispensary facilities, and in addition there has been expended since 1923 over \$16,800,000 from regular fiscal funds for improvements and extensions to veterans facilities. At the close of the fiscal year there were under construction the following major projects: (a) 275 new hospital beds at Augusta, Maine, (b) a 297-bed hospital at Batavia, N. Y., (c) a 518-bed home at Biloxi, Miss., (d) 188 additional hospital beds at Coatesville, Pa., (e) a 300-bed hospital at Des Moines, Iowa, (f) a 258-bed hospital at Fayetteville, Ark., (g) 199 additional hospital beds at Fort Lyon, Colorado, (h)

748 new hospital beds at Leavenworth, Kan., (i) 56 additional hospital beds at Rutland Heights, Miss., (j) a 334 bed hospital at San Francisco, (k) 104 new hospital beds at Tuscaloosa, Ala. The construction under way at Leavenworth, Kan., will result in a net increase of 383 beds, and at Tuscaloosa, Ala., 77 beds. The daily cost of operation per patient for hospitals used principally for the treatment of tuberculosis is \$4.61 (a reduction of 22 cents over last year), for hospitals for the treatment of neuropsychiatric diseases, \$2.12 (a decrease of 33 cents) for all general hospitals, \$3.48, and for all types of hospitals, \$2.99.

The field facilities of the Veterans' Administration made 1,350,452 physical examinations during the year for outpatient purposes, a decrease of 707,260 of the number made during the previous year. Of this number, 28,291 were dental examinations. About 94 per cent of the medical examinations and 81 per cent of the dental examinations were made by physicians on a salary basis. The medical and dental treatments rendered by physicians on a salary basis were 75.3 per cent and 71.3 per cent, respectively, of the total treatments. At the end of the fiscal year there were 5,739 beneficiaries under the supervision of follow-up nurses. General Hines states that the material decrease of the number of examinations made for outpatient purposes was due largely to the act of Congress approved March 20, 1933, and the regulations issued thereunder, which prescribed new eligibility requirements for entitlement to certain benefits.

Dental services rendered in Veterans Administration clinics during the year, if computed on a fee basis would have cost \$1,700,910, whereas the actual cost of furnishing this relief was \$869,708.52 thereby resulting, it is said in a saving of almost 50 per cent. The number of beneficiaries that received dental treatment during the year was 57,018, an increase of 20,232 over the previous year, due largely to including for the first time dental work furnished by clinics at Veterans' Administration homes. At the close of the year there were 158 full time and 3 part time dental officers on duty with the Veterans Administration.

Although 118 years have elapsed since the close of the War of 1812, there are yet seven persons receiving pensions on account of services rendered by soldiers in that war and there were still 415 widows of Mexican War veterans on the pension roll. At the close of the year, pensions were being paid to 23,863 veterans of the Civil War, representing a reduction of 7,209 since the close of the previous year. There were also on the pension rolls 125,638 widows and minor or helpless children of veterans of the Civil War, a decrease of 14,286. The grand total disbursements for pensions on account of the Civil War to June 30, 1933, was \$7,698,594,101.77. The estimated amount paid to pensioners of all wars and the regular establishment from the year 1790 to June 30, 1933, is \$8,871,483,951.58. The total number of pensioners on the roll at the end of this year was 416,840, a decrease of 21,101 over the previous year, of the total, 174,121 were widows and dependents of veterans and 566 were army nurses.

The seventy-third Congress of the United States in an act approved March 20, 1933, repealed all laws granting compensation to veterans of the World War for disabilities incurred in service and in place thereof provided for the payment of pensions effective July 1, 1933. General Hines summarizes the eligibility requirements and the rates established for pensions. Compensation was being paid, June 30, 1933, to 336,710 veterans for disabilities directly or presumptively resulting from service in the World War, an increase of 8,052 over the previous year, and the disbursement for this purpose during the year was \$184,824,665.79, a decrease of about four and three-fourth millions of dollars. The average monthly value of all compensation awards at the end of the year was \$43.70, a decrease of 42 cents over the corresponding date of last year. The major disabilities for which veterans are receiving compensation are neuropsychiatric diseases (21 per cent), tuberculosis (19 per cent), and general medical and surgical conditions (60 per cent). There were 2,966 women veterans receiving compensation June 30, 1933, an increase of 62 over a year ago, of these women, 2,424 were army nurses and 122 navy nurses. June 30, 1933 compensation was being paid to the beneficiaries of 98,628 veterans who died in service or as a result of disabilities or injuries incurred in service during the World War, an increase of 1,180 cases over the previous years. Death claims have been paid to date to the beneficiaries of 128,818 deceased veterans. The principal causes of death of veterans who died as a result of service and whose dependents now receive benefits was tuberculosis 30 per cent, injuries 28 per cent, and diseases of the respiratory system 25 per cent (largely influenza contracted during the 1918 epi-

demic). Regular monthly payments were being made, June 30, 1933, to 6,007 emergency officers who incurred disabilities of 30 per cent or more in the World War, a decrease of 408 over the previous year, which decrease was due, it is said, to an act of Congress approved June 30, 1932. There were 616,069 government life converted insurance policies in force at the close of this fiscal year.

The Veterans' Administration, June 12, 1933, began a selection of veterans to compose the veterans' contingent for emergency conservation work. Later the authority for enrolling veterans in this work was extended and 26,838 selected veterans were in work and conditioning camps, July 31, 1933. The hospital facilities controlled by the Veterans' Administration were made available for the treatment of employees of the Civilian Conservation Corps, and on June 30, 1933, there were 201 of these men under treatment in these facilities.

The number of employees on the rolls of the Veterans' Administration, June 30, 1933, was 35,467, whose annual aggregate gross salaries totaled about fifty-eight and a half million dollars, including allowances but excluding compensation paid per diem and per hour employees. This was a decrease of 1,351 employees at the close of the previous fiscal year. The personnel in the central office of the Veterans' Administration decreased from 5,372 to 5,052 during the year, and the personnel on duty at field stations decreased from 31,446 to 30,415, a reduction of 1,031 employees. The actual net disbursements of the Veterans' Administration for all purposes for the activities under its jurisdiction during the fiscal year totaled \$868,688,479.42, of which amount \$13,517,369.43 was for new hospitals and domiciliary facilities.

General Hines summarizes regulations that grew out of the act of Congress of March 20, 1933, tending toward the administration's broad economy program. On June 16, 1933, Congress further liberalized the act of March 20, 1933, and the regulations issued to that time. This act extended protection within defined limits in the several classes of pensions previously awarded to veterans and their dependents of the World War and the Spanish-American War and set up boards of review throughout the country for the final determination, subject to appeal, of veterans' claims, in which presumptive service connection had hitherto been granted under the World War veterans' act of 1924 as amended. Congress in this act appropriated \$531,988,000 for the administration of veterans relief (exclusive of the appropriation for the adjusted service certificate fund) for the fiscal year 1934 which was a reduction of some \$338,000,000 in the 1934 appropriation previously sought for the same purpose.

Included in the report is a tabulated survey of all government hospitals showing, among other things, their locations and the locations of the nearest government hospital, the capital investment in each hospital, the number and age of the patient buildings, the beds available, and the general nature of the medical work.

Veterans' Relief Regulations Modified

President Roosevelt announced, January 19, it is reported, certain modifications of the regulations providing for veterans' relief. The changes affect 228,000 veterans and add \$21,092,000 to the cost of the Veterans' Administration bringing the total for the present fiscal year to \$510,000,000. The several amendments to the regulations affecting the veterans provide for:

1. Increase from \$90 to \$100 in pensions for veterans suffering total service connected disability, and proportionate increases for those suffering less than total service connected disability.

2. Liberalized provision for hospitalization of veterans in non-service-connected emergency cases in which patient cannot pay.

3. Granting of \$15 monthly pensions to Spanish-American War veterans in service ninety days, discharged for disability incurred in less than ninety days, or who are now 50 per cent disabled regardless of service connection or age.

4. Increase from \$15 to \$100 in funeral allowance for deceased war veterans.

5. Elimination of provision requiring veterans suffering non-service-connected disability, not due to their own misconduct to prove minimum of ninety day service before granting of \$30 monthly pension.

6. Restoration of former pension rates to widows of regular army officers and enlisted men who died of disabilities incurred in line of duty.

7. Modification of rule prohibiting payment of pension of federal employees receiving salaries more than \$50 a month and granting pension to single employees paid not over \$1,000 a year or married employees not over \$2,500 a year.

The Relation of Brain and Mental Ability

Dr H L Gordon visiting physician to the Nairobi Mental Hospital, Nairobi Kenya Colony, determined the cranial capacity of 3444 unselected natives representing the average of the Kenya population. The average cubic capacity was 1316 cc against the European 1481. He also found that from the ages 10 to 20 years the average yearly growth of the native brain was 8.5 cc against the European 17.7. Further after puberty the curve of growth of the European brain rises steeply but that of the native scarcely at all. The measurements and statistical data were submitted to Mr Walter, statistician to the conference of East African governors. Dr Gordon carried his observations into the laboratory with the expert help of Dr F W Vint pathologist to the Kenya government. He found that the brains of 100 normal males averaged 150 Gm less than Europeans. Dr Vint's results (to be published in the *Journal of Anatomy*) showed that the cortex of the native brain was 15 per cent less than of the European and that its cells were smaller, less well formed and less well arranged than those of the European. Further, although there was no reduction in the number of cells in any given area the native cortex showed predominance of undifferentiated cells. Finally, Dr Gordon found that, while dementia precox is unknown among natives living their own life every native in which it occurred had received some European education. In view of the rapid introduction of European civilization into Africa, these observations are important. Dr Gordon holds that the hand of science with all its power has not yet been held out to enable the native to rise.

Dr Cyril Burt, professor of psychology at University College, London, disagrees with the conclusion that efforts to educate the natives may induce insanity because it is contrary to current theories and current practice. The notion that mental ability can be graded by measuring the skull has been abandoned. The correlation between skull capacity and inborn intelligence is certainly positive but far too small to be of diagnostic value. The skull capacity varies far more closely with physical characteristics—height weight age sex, race—than with mental characteristics. The greater part of the brain is concerned with physical and not intellectual activities. Dr Vint's observations on the cells of the cortex are more suggestive but he is far more cautious in drawing psychologic inferences than Dr Gordon and says that 'the functions of the human brain are still wrapped in mystery'. It is commonplace among psychologists today that mental characteristics should be judged by mental symptoms, not by physical. Professor Burt quotes from Dr Oliver, who has recently described in the *East African Medical Journal* tests performed in two large schools in Kenya, one native and the other European. He found that the average native intelligence was only about 85 per cent of the European, nevertheless 14 per cent of the natives actually surpassed the European average. Moreover the fathers of the European children were largely government official and professional men which should give a somewhat high European standard.

Prof Julian Huxley points out that brain weights of individuals or types are to be compared only in terms of relative brain size. Lapique showed that for different types of mammals or for the sexes the brain varies as the body weight raised to the power 0.56. When men and women are so compared their "coefficient of brains" or relative brain size is identical,

though woman's brain is distinctly the smaller. The average size of the natives measured by Dr Gordon appears to have been much less than that of Europeans, which to some extent would account for smaller brains. Professor Huxley thinks that the abler natives are perfectly capable of profiting by the best education that can be given them. Prof J B S Haldane satirizes Dr Gordon's conclusion. He points out that Martin found that the average capacity of the Eskimo brain is 1,563 cc, and thus exceeds the European. If the Kenya natives are to be protected from European education Europe should also be protected against the disintegrating effects of Eskimo culture!

The Persecution of German Scientists

At a meeting of the council of the Association of University Teachers, held at the Imperial College of Science and Technology, Prof Frank Smith of the University of Leeds said in his presidential address that freedom to teach, to learn and to investigate was the primary requirement of intellectual life. Recently in Germany race and political partisanship had been exalted above the ideal of universal learning. Germany could boast a great educational tradition, but now in an orgy of ferocious and narrow nationalism scholars, some of them among the most distinguished in the world were dismissed because they did not satisfy standards of race religion or political faith.

Dr Erwin Schrodinger professor of theoretical physics at the Friedrich Wilhelm University Berlin had to leave Germany but had found hospitality at Magdalen College, Oxford where he was elected to a supernumerary fellowship. The idea that an electron is in some way connected with a wave motion of definite frequency depending on its speed, was brought forward in 1925 by Louis de Broglie. Schrodinger found out the 'wave equation' for these waves. He has been awarded the Nobel prize in physics for furthering a new development of the atom theory. The latest estimate gives the number of refugees from Germany to other countries as 60,000 of whom 51,000 are Jews. Nearly all the medical refugees are Jews but only about half of the scientific refugees. These figures show the political nature of the persecution which is directed against all persons of pacifist or liberal views.

The Campaign Against Noise

As stated in previous letters the evil of the great increase of noise in recent years has led to organized effort to reduce it. Two societies were formed—the Anti Noise League and the Noise Abatement Association. They have been working in close alliance and have now decided to amalgamate. The Anti-Noise League which came into existence scarcely three months ago now has a membership of over 2,000 which includes Lord Horder and many other well known people. People in all walks of life gave ready support and a donation has just been received from the Clothworkers Company, one of the ancient City Livery companies.

Preventive Medicine in East Africa

The great work of building a bridge across the Zambesi in East Africa which, with its approaches measures 2½ miles and adapting the railway line accordingly is now in progress. Elaborate precautions were taken to protect the health of the workers in this malarious district. Before starting, the railway authorities sought the advice of the Ross Institute of Tropical Hygiene with reference to the sites for stations on the extension of the railway to Domira its terminus on Lake Nyasa. At the sea terminus the Portuguese government asked advice on the control of malaria in the port of Beira. When the construction camp, now like a small town was being laid out it was realized that unless special precautions were taken the climate and its fevers would take a heavy toll. Under the guidance of Mr C R Harrison, an expert with much successful work to his credit in Malaya and the copper mines in

Rhodesia, a complete system of antimalarial drains was constructed, every precaution was taken to prevent mosquitoes breeding in the vicinity of the camp, and there has been only one case of malaria among the Europeans. Hospitals have been built. The health of the native workmen has been so good that only a small percentage of admissions to the hospital have been due to illness, the rest being largely accident cases.

Automobile Fatalities

Sir Henry Dickens, son of the great novelist, who was a retired judge and 84 years of age, was knocked down by a motorcycle while crossing the Chelsea embankment, sustaining fractures and other injuries. He died in a hospital. A curious fact is that when asked by a policeman for his address he gave an address where he had not lived for ten years. At the inquest the coroner said that he often found that an injured person after an accident gave an address where he had previously lived. This seems to be an example of loss of memory for recent events. The coroner also stated that he had had in his own district of the metropolis no fewer than thirteen deaths from automobile accidents in the last few days.

The Birth Rate Is Still Falling

The Registrar-Generals' Statistical Review for 1932, which has just been issued, shows that the birth rate for England and Wales was 15.3 per thousand, which was 0.5 below that for 1931, the lowest previously recorded, and therefore was a new low record. The death rate was 12 per thousand, 0.3 below the rate for 1931 but 0.6 above that for 1930, but the 1930 rate was the lowest ever recorded and was largely due to an exceptionally mild winter. The death rate of infants under 1 year was 65 per thousand births, as compared with 66 in 1931 and 60 in 1930. Traffic accidents due to mechanical vehicles were responsible for 5,671 deaths, against 4,452, 5,196, 5,792, 6,342 and 5,892 in the preceding five years. The death rate from cancer was 1,510 per million living against 1,484 in 1931. If allowance is made for the higher age constitution of the population, the increase becomes much smaller. Tuberculosis again furnished a new low record, 837 per million. Puerperal sepsis was the cause of 155 deaths per thousand labors, and other "accidents of pregnancy and childbirth" gave a rate of 2.49. The deaths from influenza numbered 13,156, against 14,409 in 1931, 5,019 in 1930 and 29,074 in 1929.

Control of Medical Service and Child Marriage in India

In a debate in the house of commons on the appointment of a committee to consider the future government of India the Duchess of Athol pointed out that, since the transference of certain public health matters to Indian management grave deterioration had occurred. An ex-principal of the medical college at Lahore told a similar committee, at the last session, that professors were appointed who had no claim to such posts. The present professor of physiology was selected in spite of the principal's opinion in writing that he was unfit for the post. He had never acted as a demonstrator and had no qualifications to teach the subject. He informed the principal that all that he knew of physiology was what he had learned many years ago in his ordinary medical course and would have to start to read up on it. Another man was sent to officiate for twelve months as professor of midwifery and gynecology. The gynecological operations performed in the Lahore College hospitals are mainly abdominal. This man had no knowledge of the technique of abdominal surgery. He had never done an important abdominal operation. He had to leave most of the operations to his house surgeon and when he did operate the house surgeon had to supervise. Yet his appointment meant that he was the specialist for the province.

Another speaker, Miss Rathbone, a philanthropist said that the Indian census report for 1931, which had lately reached England showed that the disparity between females and males in India had steadily increased during the last thirty years. This was attributed in the report to the unsatisfactory conditions of life of young girls. Child marriage was the great evil. The government made three attempts to deal with the problem of early consummation but its efforts were nullified by Indian opposition. The Sarda act to prevent this scandal was so weakened to placate the opposition that it proved almost unworkable. In the six months following its passage 4,000,000 girls were hurried into matrimony. The number of wives under 14 in India had risen from 8,500,000 in the census of 1921 to 13,500,000 in the recent census. The number of child widows under 5 years of age had increased from 15,000 to 30,000. These shocking conditions resulted, according to the recent census, in 200,000 deaths in childbirth every year.

Code of Signals for Medical Aid at Sea

The merchant shipping act requires that every ship shall carry a medicine chest containing certain quantities of specified drugs and medical appliances, as well as an official publication, the 'Ship Captain's Medical Guide'. Every ship engaged in foreign trade carrying more than 100 men, whether as passengers or crew, must carry a doctor. This means that the vast majority of ships have none. Since the introduction of radio broadcasting ship masters when confronted by serious illness have sought medical advice from other ships which may be within range. But it often happens that they cannot give the details necessary for the doctor to make a diagnosis, especially between ships of different nationality. The new "International Code of Signals," in force with the coming of the new year, contains a 'case stating system' designed to deal with the difficulty. There are about 1,000 signals to be made by five-letter groups. Instructions are given to assist the ship's master in framing his message and the doctor in replying. The master will consult sections 1 to 20 and after he examines the patient, will frame his message in the sequence of the code. The master is advised not to give anything about which he is doubtful. Doctors are advised to confine their treatment as nearly as possible to the limits of the 'medical guides'. The code has been compiled by a committee consisting of representatives of England, France, Germany, Italy, Japan, Norway, Spain and Sweden.

The Abuse of Hospital Privileges by the Wealthy Class

The surgeons are protesting against the abuses that have arisen in the admission of well-to-do patients to the public hospitals whereby their private interests are greatly injured. In France, the public hospitals are reserved for the indigent. The expenses of the hospitals have increased enormously, during recent years by reason of the higher wages paid the nursing personnel, and the application of the new social laws more particularly social insurance, which is a very costly system and the eight-hour day law which has made it necessary to double the nursing personnel. The municipal councils pay the cost of hospital treatment for indigent patients, and furthermore, the budget of the city of Paris grants to the administration de l'assistance publique parisienne an annual appropriation exceeding 40,000,000 francs (\$2,400,000) and yet the Assistance publique has a deficit. Many of the poorer communes are in arrears in paying the hospital charges for their respective patients. The well-to-do class is not as reluctant as formerly about being cared for in the public hospitals, since for a small supplementary charge a private room can be

secured. It pays the fixed charges to the hospital which is quite content to enter to this prompt paying clientele. The sums received as surgeon fees are clear profit since the surgeon is paid a fixed annual salary by the administration and he is prohibited from accepting fees from patients. The surgeons of Paris thus find their incomes diminished. They demand energetically that the public hospitals be reserved as formerly for the indigent that is to say for persons listed at the Bureau of Charities or who furnish proof that they pay only a minimal house rent. The scandalous spectacle of rich patients coming to the hospital in a luxurious car to consult a specialist for the sum of sixty cents, the fee established for the poor or undergoing an operation for appendicitis or fibroma at the hospital free of charge by the same surgeon that they consulted at home, must cease.

Radium Treatment of Inoperable Gastric Cancers

Professor Gosset in collaboration with Messrs. Monod and Regnaud reported to the Academy the results of using radium *a distance* in thirty one cases of inoperable gastric cancer. The results were not brilliant. The chief interest of the report lies in the fact that the high reputation of Mr. Gosset justifies the conclusion that others are not likely to succeed better in this field. Mr. Regnaud had applied a relatively large quantity of radium (4 Gm.), which was distributed over a rectangular plate with an area of from 125 to 160 square centimeters and applied at a distance of 10 cm. from the skin. The rays penetrated through multiple cutaneous surfaces epigastric dorsal and laterotransversal. The sittings for irradiation with a duration of two hours each were distributed according to series over a total period decided on tentatively in advance but variable in keeping with the tolerance of the patient. In seven cases (54 per cent) no improvement was secured. In seven cases the treatment gave some relief but without prolonging life. In seven cases (22 per cent) there was considerable improvement and life was prolonged varying periods of time. Two of these patients are still living, one appears to be cured after a space of six and a half years. The other patient has survived four years and nine months. Two factors influenced unfavorably the results: (1) the bad general condition of the patients, who could not endure the dose necessary to bring about a notable retrogression of the cancer; (2) the resistance to radium displayed by the cancerous tissue. The resistance varying greatly in different cancers, it is as yet impossible to determine in advance what the resistance will be on the basis of the histologic type of the tumor as there is a lack of documentation in such cases. For the histologic examination to have full value, the tissues must be taken from the tumor itself and not from the perigastric glands, which are often enlarged although not invaded by the cancer. Since the resection from removal of a fragment of tumor may be dangerous, the most interesting cases to study are the recurrences after gastrectomy, when the portion removed by operation has been carefully examined. Surgical exploration will be supplemented by gastro-enterostomy if need be, and by fixation of the stomach to the anterior wall of the abdomen to permit bench marking of the tumor with reference to a future incision. If a cancer is operable by gastrectomy or pylorotomy, excision is preferable to radium therapy the latter method being reserved for cancers that are actually inextirpable.

Strychnine in the Treatment of Barbitol Poisoning

The Society of the Physicians of the Hospitals of Paris devoted recently a long discussion to poisonings due to barbitol compounds which have become exceedingly numerous. Several cases occur every week in Paris, where these products may be secured in pharmacies (in spite of regulations to the contrary) without a prescription. The antagonism of strychnine and bar-

bitol compounds is well known. Professor Ide has gone so far as to say that death should no longer result from barbitol or phenobarbitol if strychnine is properly employed to combat it. Lienne Bernard and Leroux Robert administered without success 0.38 Gm. of strychnine, over a period of thirty hours to a patient poisoned by a heavy dose of phenobarbitol. D. Oebnitz, Balestre Brugiere and Raibauch (of Nice) administered 0.44 Gm. of strychnine, within fifty-seven hours, to a man aged 60 who had ingested 10 Gm. of barbitol and who succumbed whereas a woman aged 47, who had taken 15 Gm. recovered following a dose of 0.06 Gm. of strychnine given within twenty hours. Louis Ramond and Jean Delhy reported a case in which a person poisoned by barbitol died in spite of the enormous amount of strychnine (0.62 Gm.) administered within three days. Flandin and Jean Bernard attended a peculiar case. A woman having ingested 15 Gm. of phenobarbitol was brought to the hospital in coma. She was given intravenously 0.20 Gm. of strychnine during the first three hours and the medication was continued up to 0.53 Gm. in thirteen hours and 1.30 Gm. in sixty-seven hours until an alarming convulsive crisis appeared while the coma continued. She succumbed the sixth day in coma. It was apparent from this discussion that barbitol poisonings present variable degrees of gravity. Prolonged hyperthermia is always a bad prognosis. In one case the temperature continued to rise up to 42° C (107.6° F), which was reached two hours after death. Prompt treatment and the immediate use of large doses are very important. But the dose is difficult to determine *a priori*; then too, it is not always known when a patient arrives in a state of coma just what amount of barbitol has been ingested. Paraf Delhy and Macrez in the case of a woman who had ingested 10 Gm. of barbitol and 0.10 Gm. of phenobarbitol and had lapsed into coma reported that a simple dose of 0.01 Gm. of strychnine precipitated convulsions. It appears, therefore, that there is no mathematical relation between the amount of barbitol ingested and the dose of strychnine capable of neutralizing it. There is a wide range of individual receptivity, which upsets attempts to make a prognosis. The toxic dose of barbitol is 3 Gm. for some persons, and in other cases reaches 10 Gm.

Vaccination Against Tuberculosis in the Navy

The minister of the marine has created vaccination services for the application of the BCG vaccine in all the ports, and in all the cantonments of the navy, in collaboration with the local authorities. This measure will be confined for the present to children of families connected with the naval forces and to certain classes of personnel more particularly exposed to contagion.

Discussion of Roentgenologist's Cancer

Mr. Beclere addressed recently the Academy of Medicine on roentgenologist's cancer. Thirty years ago he was the first to equip his department, in the Hôpital St. Antoine with a radiologic apparatus, thus far, he has contracted only a chronic restricted radiodermatitis, without cancerization. Mr. Beclere has abandoned the conception of the irritative origin of cancer as upheld by Menetrier. He does not regard cancer as the almost inevitable result of inflammatory and hypertrophic lesions of increasing intensity. Beclere thinks that cancer is an accident associated with various nonspecific lesions, a complication that implies the development of a new factor. The roentgenologists who become affected with cancer are much in the minority, as compared with those who have manifest changes of the skin of the hands. There is no parallelism between the degree of cutaneous lesions and the presence or absence of cancer. Many roentgenologists affected with cancer have never had the slightest sign of acute radiodermatitis and presented only insidious skin changes, very slowly progressive. The term

hronic dermatitis" does not appear to fit their condition for most cases they present none of the clinical characters of inflammation. Their lesions correspond rather to those that develop following nerve injuries. They have the character of trophic disorder and reveal rather the destructive action of roentgen rays than the excitatory and irritative action. The labrous appearance and the extreme dryness of the thin skin furnish evidence of the atrophy of the hair follicles, the sebaceous glands and the sweat glands. These observations appear to support the hypothesis that cancer like tuberculosis is a disease of external origin, in spite of the fact that the microscope does not reveal the causative agent.

Professor Regaud, director of the Curie Institute, supported his conception of Mr. Becquerel with the weight of his authority. He does not, however, assume distinctly the action of an external specific agent in the genesis of cancer. He expressed the view that the roentgen rays destroy the cells but do not create inflammatory states. The cancerous lesion of the skin is an accident—an explosion, so to speak, of abnormal cellular activity, which develops at one or more points in a vast surface sometimes following a chronic inflammation but at other times in the absence of all inflammation. Regaud is opposed to the theory of a "general cancer disease." He does not believe that hereditary influences or blood changes are the chief causative factors. Evidence of this is the complete recovery that is effected by a local operation performed in time. Cancer comprises as many distinct diseases as there are tissues and organs. These are essentially local diseases although the onset may be facilitated by general causes.

PRAGUE

(From Our Regular Correspondent)

Dec 27, 1933

A Smaller Public Health Budget

The Czechoslovakian parliament has just approved of the budget for 1934. The whole budget was made up under the pressure of the strictest economy in public finances. A reduction of expenditures for public health was to be anticipated. From the highest figure of 157,000,000 crowns for the ministry of health in 1931 the appropriation was cut to 140,000,000 for 1934. While the total reduction of state expenses in comparing the year 1931 with 1934 is more than 20 per cent, public health came out with a reduction of slightly more than 10 per cent. In comparison with other branches of public administration, public health was given some preference. Only general administration, schools and justice have had a smaller reduction in the budget. All other public services, including national defense, suffered much deeper reductions of their appropriations. No material reductions in the public health personnel have been effected through the budget. As the health officers are civil service employees their salaries have been reduced on the same scale as the remuneration of other public officials. The finance administration insists only on a reduction of 10 per cent in the number of public health posts throughout the country in such a way that vacancies from death or retirement cannot be filled up to that limit. Private public health work which is subsidized in Czechoslovakia from public funds has suffered mostly from the uncertainty of future support rather than from actual lack of funds. While the state subsidies have been reduced, substantial aid to institutions supported by private associations has come from the central insurance fund which administers the sickness insurance for the whole working population of the country. This fund stepped in at this moment to preserve the voluntary public health machinery from actual collapse. On the whole the public health machinery of Czechoslovakia which has never been built up to abnormal proportions has stood up well under the attacks of hard times and consequently has proved its solid foundation.

Conference on Child Welfare

The fourth Conference on Child Welfare was held in Brno, October 28-31. These conferences were founded by Prof. E. Brubek of Brno in 1922 to promote research in child welfare by teachers, psychologists, anthropologists and physicians. The congress was a great success. The number of participants was more than 1,200. Foreign delegates came from Russia, Poland and Yugoslavia. The first section dealt with the preschool child, the second section with adolescence. The resolutions adopted dealt chiefly with public health, stressing the importance of school medical inspection, dental care, nutrition and defects of speech. A warning was formulated for teachers especially with regard to athletics, in which overstrain in children may be just as detrimental to health as too little physical culture. A striking feature of the congress was the perfect cooperation between teachers and physicians. A permanent committee will attempt to organize the next congress in two years on an even broader basis, inviting in larger numbers participants from other Slavic nations.

Professor Petřivalský's Birthday

The chief of the surgical clinic of the Brno Medical Faculty, Dr. Julius Petřivalský, has celebrated his sixtieth birthday. He is one of the few surviving pupils of the Prague school of surgeons educated by Professor Maydl. Born in Moravia, he was given the task of building up the surgical clinic when the new faculty of medicine was founded in the capital of Moravia in 1919. After graduating in Prague in 1898, he took up surgery and later studied in Germany, Switzerland, France and Belgium. He began lecturing on surgery at the Prague Faculty of Medicine in 1909 and became the chief of an independent surgical institute when the new university was founded in Brno. He formed a surgical school of his own, and his pupils occupy important university posts and leading positions in provincial hospitals. His research was devoted chiefly to cancer and to the improvement of surgical technique. Over fifty papers of his have been published, also three manuals of surgery. He is a member of many Czechoslovakian and international scientific bodies.

Industrial Diseases and the Compensation Law

A section for the study of industrial hygiene was organized recently within the Association of Czech Physicians. The impetus came from the need in medical practice resulting from the law on compensation for industrial diseases. When the law became effective in 1933, a list of twenty-five occupational diseases was made up that come under the workmen's compensation act. The sickness insurance bodies notify cases of these diseases when they last longer than twenty-six weeks, and if the claimant is disabled a pension is given in proportion to his reduced working capacity. Since this measure affects the financial interest of sickness insurance bodies, they search among their patients for cases that can be proposed for a pension. Up to the present the occupational side of the etiology of diseases has been somewhat neglected. The new law makes necessary the definition of clinical symptoms that make up a compensable case of industrial disease. The first session which was recently held heard papers on lead poisoning, the organization of first aid in large factories, and the relation of silicosis to tuberculosis. The group represents not only the Prague Faculty of Medicine but also leading physicians of provincial hospitals and medical departments of important industrial corporations.

"Patent Medicines" Unknown in Czechoslovakia

The economical control of pharmaceutical products is becoming a serious problem in Czechoslovakia. After the war an increased demand for medicines was met largely by importa-

tion from foreign countries but of late the local chemical industry has begun the production of all kinds of medicines 'Patent medicines' in the American meaning of the word are unknown in Czechoslovakia because the sale of only such medical preparations is allowed as those of which the contents have been made public. The so-called medical specialties which are related to patent medicines are only a combination of known ingredients which can be protected from competition by special authorization from public authorities. As the bureaucratic procedure to obtain this authorization is long drawn out the firms place their preparations on the market when they apply for authorization. So a number of medical specialties are on sale without authorization of the authorities. The chief hindrance to the proper regulation of this matter is the lack of endowment of public laboratories that are entrusted with the control and analysis of such preparations. A private corporation was recently formed by well known university teachers including pharmacologists, clinicians and biologists who offer their services for the control of medical specialties. This nonprofit institution will give its approval of medical specialties only in case the claims of the preparation are justified by scientific facts. Such preparations will be included in the list of medicinal eminences which the corporation will publish periodically. The cost connected with the examination of these preparations will be borne by the respective producers. The names behind the new institution guarantee impartial and authoritative work.

New Centers for the Study of Cancer

In 1932 the number of deaths due to cancer exceeded the number of deaths due to tuberculosis. A private association to combat cancer which has existed in Prague for twenty years, succeeded recently in collecting funds for the erection of a research institute. This institution is only partly subsidized by public authorities. Another cancer center is being organized in Brno where an analogous institution is approaching the completion of its own building. An association for the study of cancer has been organized also in Brno.

BERLIN

(From Our Regular Correspondent)

Dec. 11, 1934

A Survey of Left-Handed Students

Professor Bethe, physiologist, of Frankfurt, has completed some research on the question as to whether there exists a superiority of one hemisphere of the brain and as to whether the left hemisphere is superior to the right. He was led to make this study by the observation that persons whose right arm was amputated during the World War adapted themselves rapidly to the use of the left arm. Experimenting on himself he became accustomed to use his left hand but only after a lapse of several years. In contrast, he saw that when a person is suddenly deprived of an arm, the ability to use the other arm develops rapidly. The alleged predominance of one hemisphere of the brain over the other hemisphere cannot be harmonized with this fact. Left-handedness is more common than is generally supposed. Among 266,000 soldiers, 10,300 were left-handed, or 3.9 per cent. The proportion of left-handed and of right-handed young children is identical, ranging around 17 per cent, the remainder are ambidextrous. With increasing age, the proportion shifts toward the side of right handedness. Another series of statistics lists 25 per cent of a group of children as left-handed. Bethe instituted experiments on a large scale on students and reached the conclusion that there is absolutely no predominance of the right side in the use of the limbs. His investigations showed the proportion of genuine right-handed and left-handed subjects to be as 20 to 25 per

cent. The next thing to be decided is whether the dominance of one side is of a primary or an acquired character. A frequently observed fact is that in aphasic plegia or a left-handed child in whom the speech center would be assumed to be in the right hemisphere the paralysis does not affect the left side. Experiments have established that in the frog and in the turtle after removal of a labyrinth, a lateral diversion of the leg or fin respectively, develop, which after extirpation of the second labyrinth continues unchanged as a pronounced acquired modification of behavior. Similar observations have been made on the dog which after removal of one cerebellar hemisphere develops the staggers and retain the disorder following removal of the other hemisphere. Therefore it may be concluded that central manifestations occur as a result of acquired functional procedure. Other experiments point to the same conclusion. The view that left-handed persons are exposed to suffer from physical deformities, mental backwardness, epilepsy, criminal tendency, strabismus, deaf-mutism, stuttering, and the like is discredited by the fact that many distinguished men (for example Leonardo da Vinci and the surgeon Ludwig Rehn) were left-handed. Bethe addressed a questionnaire to four universities among the members of the faculty of which 20 per cent were left-handed. This is a far greater percentage than is commonly supposed to exist. Furthermore the left-handed persons, as a survey showed were better in the examinations, on the average than were the other cases. These observations serve to show that there is no evidence for an unequivocal superiority of one hemisphere of the brain over the other.

Birth Rates and Illegitimate Births

In 1932, Germany, Italy and Poland had a marked decline in the birth rate. In the German Reich the number of live births receded by 53,600. In Italy the number of living births was 34,150 fewer than in 1931 so that in 1932 the birth rate for Italy was only 23.8 per thousand as compared with 24.9 births the previous year and 26.7 births in 1930. In Poland in 1931 50,000 fewer births were recorded and in 1932 there was a further decline of nearly 34,000 so that the birth rate of Poland dropped over the two year period from 32.3 (1930) to 28.7 per thousand of population. In the remaining countries of western, central and northern Europe the decline in the birth rate ranged from 0.2 to 0.7 per thousand. France had a decline in its birth rate of only 0.2 per thousand. In Sweden and Hungary the birth rate was only 0.2 and 0.3 per thousand of population respectively, lower than in 1931, whereas Great Britain and Czechoslovakia showed a decline of 0.5 per thousand and Austria a drop of 0.7 per thousand. Unchanged birth rates were recorded in the Netherlands and in Switzerland. The countries of lowest birth rates at present are the German Reich, Austria, Sweden and Great Britain with birth rates ranging from 14.5 to 15.8 per thousand. France (with a birth rate of 17.2), Belgium (18.1) and Switzerland (16.7) have in recent years passed out of the group of nations with the lowest birth rates. The birth rates in Norway (16.7), Denmark (18.0) and Finland (19.5) together with Lithuania and Estonia range around that of France and in some cases exceed it. In countries bordering on this area limitation of births is making further progress particularly in Czechoslovakia, Hungary and Italy, which countries report in contrast with former high rates, birth rates of from 21 to 24 per thousand, which are lower than the birth rate of the German Reich in 1923 (26.9). The birth rates in the countries of the Iberian peninsula (28.3 and 30.7) and in eastern and southeastern Europe are still high. There appears to be evidence, however, that the demographic pressure of the Slavic races of the East will in the near future lose considerable of its force. It may be added that in 1932 the population of Japan increased by 1,007,848 (in 1931 by 861,534).

The percentage of illegitimate births in Germany (12.1) isceeded by that of only one European country (Sweden with percentage of 16.1). The corresponding percentage in Greece 14, Bulgaria 40, Great Britain, 46, Italy 49, Norway, 1, France, 84, and Denmark and Czechoslovakia 107.

Requirements to Practice in Health Insurance Societies

The regulations of the new government concerning the admission of non-Aryan physicians to practice in the *Krankenkassen* have undergone several changes. It will be recalled that of physicians of Jewish extraction only those have been admitted late who were in practice before the outbreak of the war together with those who fought at the front in the German army. Under date of November 20, the federal minister of labor decreed that non-Aryan women physicians whose husbands died in the World War and whose admission was prevented solely on account of their non-Aryan descent shall be readmitted to panel practice. It has been further decreed that in cities with more than 100,000 inhabitants, non-Aryan physicians and Aryan physicians and women physicians who have a non-Aryan spouse shall not be admitted until further notice. In these cities, non-Aryan physicians who within the meaning of the provisions, are to be regarded as front line combatants cannot be admitted since the promulgation of the decree of Nov. 20, 1933. The purpose of this provision is to relieve the unbalanced conditions that exist, primarily in the metropolitan cities, between the number of non-Aryan and Aryan physicians. Dr. Wagner, federal leader of the physicians, asked recently for cooperation in the settlement of the difficult Berlin problems, and particularly for the abolition of the unendurable condition in the federal capital today, where there are still more than 60 per cent of the physicians engaged in panel practice who are non-Aryans.

An Investigation of Honorary Titles

In the past fourteen years, an unusually large number of honorary doctor titles have been granted by German universities. The ministers of public instruction in Prussia, Bavaria and Baden have decided to institute an inquiry, for it has been said that honorary titles have been conferred frequently for political reasons rather than for scientific attainments. It was further decreed that a supplementary order be appended to the regulations for the conferring of titles which shall provide for the cancelation of the doctor title under given conditions. This order is aimed at persons whose activities in foreign countries are detrimental to Germany's welfare and makes it possible to deprive such persons of their German citizenship.

The Medical Press of Germany

It was previously mentioned (*THE JOURNAL*, Sept. 2, 1933, p. 792) that an endeavor was to be made by the government to bring about greater uniformity in the medical press of the provinces. Dr. Wagner, the federally appointed leader of the German medical profession, has now ordered that from Jan. 1, 1934 in addition to the official organ of the federally controlled leagues of German physicians, the *Deutsches Arzteblatt* and the journal of the national-socialist medical league *Ziel und Weg*, only thirteen provincial journals will be published, in place of the previous thirty-two. All these journals will bear the title *Arzteblatt*, with a statement as to what section of the country they are designed to serve. For example one will serve all of Bavaria, and another will serve Wurttemberg and Baden in common. The contracts will be made with the publishing houses by the federations of the panel physicians who serve the *Krankenkassen*. All contracts for the whole reich to be on the same financial basis so that underbidding or overcharging on the part of the various publishing houses will be impossible.

MOSCOW

Nov. 19, 1933

Anniversary of the Institute of Experimental Medicine

The All-Union Institute of Experimental Medicine was established Oct. 15, 1932, by a special decree of the council of the People's Commissars of the Soviet Union. The institute has already developed a large scientific and practical program. In the clinic of the institute, I. P. Pavlov has studied the function of the nervous system of sane people by the method of conditional reflexes. Prof. A. G. Gourvitch conducted a study on the early diagnosis and treatment of cancer, which he reported at the International Congress of Cancer in Madrid. Prof. P. I. Zdrovovsky studied experimental meningitis on rabbits, also the development of arteriosclerosis, its prophylaxis and treatment.

The institute has organized a museum. In order to study the history of the biologic sciences, a commission of professors has been organized. New buildings will be erected for pediatric and mental clinics.

Physicians Visit Poland

A delegation of Soviet physicians was present at the Polish Congress of Physicians at Posen, September 12-15. The members of the delegation were Profs. A. S. Abrikosov, B. I. Lavrentiev and I. A. Mendeleyeva and Dozent A. A. Bagdasarov. After the congress was closed the delegation visited Warsaw. In honor of the delegation the Polish minister of labor gave a banquet.

This trip was the first of its kind since the October revolution.

Professors Honored

At a November meeting, the Central Executive Committee of the Russian Soviet Republic awarded the title "Honorable Science Workers" to Profs. M. A. Averbach and A. A. Kisel of the Second Moscow Medical Institute and to Prof. V. P. Osipov, director of the institute for the study of the brain. Professor Averbach is a prominent ophthalmologist. He founded a school of ophthalmology, organized a large hospital for eye diseases, and is the permanent president of the Moscow Ophthalmologic Society. Professor Averbach's scientific work is known throughout the world. Professor Alexander A. Kisel organized the children's clinic of the Second Moscow Medical Institute, where he worked about twenty years. He has written many scientific works and is the permanent president of the All-Union and Moscow district societies of pediatricians. Prof. Victor P. Osipov is well known in the fields of psychiatry. Since 1929 he has been the director of the State Institute for the Study of the Brain at Leningrad.

Marriages

WILLIAM WARRINER WOODRUFF, Saranac Lake, N. Y., to Miss Gertrude Strathbucker of Milwaukee at Detroit, Oct. 31, 1933.

ARTHUR ALLEN CANTWELL, Shawano, Wis., to Miss Alice Davis of Bozeman, Mont., in Wilmette, Ill., Dec. 23, 1933.

JOHN HENRY BLEKKEING to Miss Dina Theodora Arentsen, both of Oostburg, Wis., Nov. 14, 1933.

PHILIP R. McGRATH to Miss Margaret Mary Watson, both of Peoria, Ill., Oct. 19, 1933.

FRANK T. BOWER, Hattiesburg, Miss., to Miss Hazel Draughn, Nov. 23, 1933.

SAMUEL FOX, Lawrence, Mass., to Miss Esther Goose of Chelsea, recently.

EDWARD JACOBS to Miss Anne Seeman, both of New York, Dec. 23, 1933.

Deaths

William West Grant, Denver, Long Island College Hospital, Brooklyn, 1868, Trustee of the American Medical Association 1901-1916, member and past president of the Colorado State Medical Society, Western Surgical Association and the Denver City and County Medical Society, chairman of the state committee on medical defense, fellow and one of the founders of the American College of Surgeons, served during the Civil and World wars, at one time lecturer on clinical and surgical gynecology, University of Colorado School of Medicine, surgeon to St. Luke's Hospital, aged 87, died, January 8.

Charles Franklin Eikenbary ♂ Seattle, Rush Medical College, Chicago, 1903, in 1926 Member of the House of Delegates of the American Medical Association, past president and secretary of the Spokane County Medical Society, member of the American Orthopedic Association and fellow of the American College of Surgeons, served during the World War, chief of staff of Children's Orthopedic Hospital and on the staff of the Swedish Hospital, formerly orthopedic surgeon to St. Luke's, Sacred Heart and the Deaconess hospitals, Spokane, aged 56, died, Dec. 31, 1933, of pneumonia.

Delbert Linscott Jackson ♂ Boston, Harvard University Medical School, Boston, 1908, member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, and fellow of the American College of Surgeons, formerly assistant in obstetrics at his alma mater, on the staffs of the Boston Lying-in Hospital, Massachusetts Women's and New England Baptist hospitals, Chelsea (Mass.) Memorial Hospital, Chote Memorial Hospital, Woburn, Jordan Hospital, Plymouth and the Frammingham Union Hospital, Frammingham, aged 52, died, January 1, of heart disease.

Dennis Edward Sullivan ♂ Concord, N. H., Bellevue Hospital Medical College, New York, 1885, Member of the House of Delegates of the American Medical Association, 1914-1915, 1920-1922, 1924-1928, 1930-1933, since 1906 secretary of the New Hampshire Medical Society, member of the state board of health since 1913, member of the board of education 1908-1917, served during the World War, on the staffs of the New Hampshire Memorial Hospital for Women and Children and the Margaret Pillsbury General Hospital, aged 70, died suddenly, January 19.

Herbert Vergil Scarborough, Lyons, Kan., College of Physicians and Surgeons, Keokuk, Iowa, 1902, member of the Kansas Medical Society and the Indiana State Medical Association, director of the Henrietta Brown Memorial Foundation, formerly superintendent of the State Sanatorium for Tuberculosis, Oakdale, Iowa, and the Sunnyside Sanatorium at Oaklandon, Ind., aged 57, died, January 1, at Norton of heart disease.

Irving Howard Cameron, Toronto, Ont., Canada, University of Toronto Faculty of Medicine, 1874, emeritus professor of surgery and clinical surgery at his alma mater, served with the Canadian Army during the World War, fellow of the American College of Surgeons, surgeon to St. John's Hospital and consulting surgeon to the Toronto General Hospital and the Hospital for Sick Children, aged 78, died Dec. 15, 1933.

Edmund Michael Baehr, Cincinnati, Medical College of Ohio, Cincinnati, 1901, associate professor of physiology, University of Cincinnati College of Medicine, member of the American Psychiatric Association, served during the World War, formerly member of the state bureau of juvenile research and the state welfare board, aged 55, was found dead, January 2, of heart disease.

Charles Bartles Smith ♂ Washington, N. J., College of Physicians and Surgeons, Baltimore, 1891, formerly mayor of Washington and member of the board of education, past president of the Warren County Medical Society, aged 66, died Dec. 19, 1933, of chronic nephritis, myocarditis, chronic cholecystitis, cerebral embolism and bronchopneumonia.

Benjamin Franklin Bond, Savannah, Ga., Atlanta College of Physicians and Surgeons, 1900, acting assistant surgeon, U. S. Public Health Service, served during the World War, for many years on the staff of the U. S. Marine Hospital, aged 56, died suddenly, Dec. 9, 1933, of angina pectoris, arteriosclerosis and diabetes mellitus.

William Ben Boyce, Escanaba, Mich., Medical Faculty of Trinity University, Toronto, 1902, member of the Michigan State Medical Society and the American Academy of Ophthal-

mology and Otolaryngology, past president of the Delta County Medical Society, on the staff of St. Francis Hospital, aged 59, died, Dec. 31, 1933, of cerebral hemorrhage.

Leon Ashley Peek ♂ West Palm Beach, Fla., College of Physicians and Surgeons, Baltimore, 1897, fellow of the American College of Surgeons, past president of the Palm Beach County Medical Society, served during the World War, on the staff of the Good Samaritan Hospital, aged 58, died, January 5, of cardiorenal disease.

Louis Henry Braafadt, Sacramento, Calif., Rush Medical College, Chicago, 1916, member of the California Medical Association and the American Association of Pathologists and Bacteriologists, formerly a medical missionary, aged 48, died Nov. 10, 1933, in the Sutter Hospital, of septicemia, following furuncle of the nose.

Frank Chambliss Johnson ♂ New Brunswick, N. J., Columbia University College of Physicians and Surgeons, New York, 1920, fellow of the American College of Physicians, on the staff of the Middlesex General Hospital, aged 39, was found dead, January 1, as the result of a fall from a precipice.

William Stockton Blue, Ottawa, Ill., Indiana Medical College School of Medicine of Purdue University, Indianapolis, 1906, veteran of the Spanish-American War, aged 55, died Dec. 24, 1933, in the Edward Hines, Jr., Hospital, Hines, Ill., of chronic myocarditis and coronary occlusion.

George Ray Hare ♂ New York, Bellevue Hospital Medical College, New York, 1898, fellow of the American College of Surgeons, surgeon to the Manhattan Eye, Ear and Throat Hospital, New York, and the Nassau Hospital, Mineola, N. Y., aged 68, died Dec. 24, 1933, of pneumonia.

Charles Penny McCabe ♂ Braintree, Mass., McGill University Faculty of Medicine, Montreal, Que., Canada, 1919, aged 39, died Dec. 15, 1933, in the Deaconess Hospital, Boston, of carcinoma of the stomach with metastases to the liver, peritoneum and left clavicle.

William Thomas Dawe ♂ Gonzales, Texas, University of Texas School of Medicine, Galveston, 1905, secretary of the Gonzales County Medical Society, served during the World War, city and county health officer, aged 59, died, Nov. 27, 1933, of sarcoma of the liver.

Herbert Battles Tanner, Eastland, Texas, Indiana Medical College, Indianapolis, 1876, member of the State Medical Association of Texas, formerly mayor and member of the school board of Kaukauna, Wis., aged 74, died Dec. 4, 1933, of tuberculous pleurisy.

Albert Levesque, St. Vincent de Paul, Que., Canada, School of Medicine and Surgery of Montreal, 1916, served during the World War, medical officer of St. Vincent de Paul penitentiary, aged 41, died, Oct. 27, 1933, of edema of the lungs.

John Hersey Fairfield, Great Falls, Mont., University of Pennsylvania School of Medicine, Philadelphia, 1880, county coroner, formerly mayor and secretary of the county and city board of health, aged 77, died, Dec. 5, 1933, of heart disease.

Charles Francis Chapman ♂ Mount Kisco, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890, on the staff of the Northern Westchester Hospital, aged 65, died Dec. 26, 1933, of heart disease.

Daniel Benton Cain ♂ Evansville, Ind., Kentucky School of Medicine, Louisville, 1893, formerly county health officer on the staffs of St. Mary's and the Protestant Deaconess hospitals, aged 70, died Dec. 24, 1933, of heart disease.

Sydney Sheppard Kellam ♂ Belle Haven, Va., University of Virginia Department of Medicine, Charlottesville, 1898, past president of the Accomac County Medical Society, aged 59, died suddenly, Dec. 12, 1933, of angina pectoris.

Thomas David Gunter ♂ West Palm Beach, Fla., University of Georgia Medical Department, Augusta, 1906, on the staff of the Good Samaritan Hospital, aged 60, was found dead, Dec. 25, 1933, of a self-inflicted bullet wound.

Samuel Reed Eaton, Battle Creek, Mich., University of Michigan Medical School, Ann Arbor, 1900, member of the Michigan State Medical Society, aged 70, died Dec. 14, 1933, of chronic bilateral pyelonephritis and uremia.

Julie B. Frankenheimer ♂ San Francisco, Cooper Medical College, San Francisco, 1898, formerly instructor and lecturer in medicine at his alma mater, aged 60, died Dec. 14, 1933, of angina pectoris, nephritis and myocarditis.

Thomas Shelby Chapman, McAlester, Okla., Louisville Medical College, 1896, member of the Oklahoma State Medical Association, formerly mayor of McAlester, aged 64, died, Dec. 11, 1933, of chronic nephritis.

Charles Werden Holbrook, East Haven, Conn., Yale University School of Medicine New Haven, 1896, member of the Connecticut State Medical Society, formerly a minister aged 77, died, Dec 18 1933, of pneumonia

Gordon William Schneider, New York Baltimore Medical College, 1913 member of the Medical Society of the State of New York, aged 45, died Dec 13 1933, in the Sydenham Hospital, of uric acid and chronic nephritis

Henry Allan Beck, Ulrichsville, Ohio Jefferson Medical College of Philadelphia, 1912 served during the World War aged 43 died, Dec 5 1933 in the U S Veterans' Hospital Aspinwall, Pa., of pulmonary tuberculosis

Roy Dudley Moore, San Francisco Barnes Medical College, St Louis 1899, member of the board of review of the Veterans' Administration, aged 56 died, Nov 24, 1933, at Los Angeles, of pulmonary tuberculosis

Clifford Earle Steckbauer Chicago, University of Illinois College of Medicine, Chicago, 1927, on the staff of the Illinois Eye and Ear Infirmary aged 35, died, Dec 28, 1933 of a self inflicted bullet wound

Stanhope M Scott, Sr, Terra Alta W Va., University of Virginia Department of Medicine, Charlottesville, 1871, aged 83 died, Sept 4, 1933 in Fairmont, of fracture of the left femur received in a fall

Fred A Collins, Vega, Texas, Arkansas Industrial University Medical Department Little Rock 1893 aged 67 died, Dec 1, 1933 in a hospital at Amarillo of diabetes mellitus and myocarditis

George Lucas Harman, Savannah Ga., Baltimore University School of Medicine, 1897 member of the Medical Association of Georgia aged 62, died, Dec 2 1933 of myocarditis

Joseph Roosevelt Breitbart, Cleveland, Cornell University Medical College, New York, 1924 on the staff of the Mount Sinai Hospital, aged 33, died, Dec 18, 1933 in Bermuda

Addison Orr Boals, Hickory Valley, Tenn Vanderbilt University School of Medicine Nashville 1889, aged 81 died Dec 30 1933, in the Baptist Hospital, of myocarditis following diphtheria

Robert Lee Clayton, Celina Texas Atlanta Medical College 1881, Tulane University of Louisiana Medical Department New Orleans 1898, aged 70, died, Dec 1, 1933, of heart disease

S E Boggs, Washington C H Ohio Starling Medical College Columbus 1882, member of the Ohio State Medical Association aged 73, died Dec 13, 1933, of heart disease

Newell Hiram Hamilton, Santa Monica, Calif., Rush Medical College Chicago 1877, aged 81, died, Nov 7, 1933, of chronic interstitial nephritis and mitral insufficiency

T C McCloud, Graham, Texas (licensed Texas, under the Act of 1907) aged 48, was found dead Dec 21, 1933, of a skull fracture received in an automobile accident

Ida B Cameron, San Francisco Hahnemann Hospital College of San Francisco, 1895, aged 67 died, Nov 27, 1933 in the Children's Hospital, of cerebral hemorrhage

Charles Maurice Stanley, Portland Maine, College of Physicians and Surgeons, Boston, 1912 aged 67, died Dec 3 1933, as the result of an automobile accident

Richard Foster, Santa Ana, Calif., Howard University College of Medicine, Washington, D C 1892 aged 75, died Nov 8, 1933, of organic heart disease

John Bentley McMillan, Detroit Detroit College of Medicine 1889, aged 76, died, January 1 in the Henry Ford Hospital of ulcer of the pylorus

Samuel Ellis, Lees Summit Mo Medical College of Ohio Cincinnati 1866 aged 98 died Oct 31, 1933 of bronchopneumonia and arteriosclerosis

William Henry Maines Jeffs, Toronto Ont Canada, Trinity Medical College Toronto, 1888 aged 69 died Nov 14 1933 of heart disease

Oscar Jones, Indianapolis Central College of Physicians and Surgeons, Indianapolis 1901, aged 56, died Dec 23 1933 of cerebral hemorrhage

Lewis S Mershon, Alhambra, Calif University of the South Medical Department, Sewanee Tenn, 1895 aged 79 died Nov 6 1933

Edgar J Farlow, Long Beach, Calif (licensed Iowa, 1886) aged 82 died, Nov 25, 1933, of coronary sclerosis

ERGOT IN PURPURA

To the Editor —In a communication under the title "Use of Ergot to Contract Capillaries in Purpura" (THE JOURNAL, Dec 30, 1933, p 2137) J C Norris mentioned the use of this solution in drachm doses, and solution of pituitary, 05 cc., hypodermically

The use of ergot in purpura is an old time remedy In the *Journal of Cutaneous and Genito-Urinary Diseases* (9 241 [July] 1891) W L Munroe tells of a peculiar exanthem following an attack of epidemic influenza The eruption consisted of a hemorrhagic exanthem Part of the treatment given was as follows

Tr ferri chloridi
Lut ergotae fl

aa m xxx i d

Ergot was not an uncommon ingredient in prescriptions used in purpuric conditions of the skin at that time, but it fell into disrepute on account of the danger of producing ergotism

JOHN G DOWNING, M D, Boston

"SCHWEIGGER'S JOURNAL FÜR CHEMIE UND PHYSIK"

To the Editor —Walton states (Historical Aspects of Enzyme Investigations, THE JOURNAL, Dec 30, 1933, p 2137), in regard to Schweigger's *Journal für Chemie und Physik* that the only available set of this journal is in the New York Public Library, at least in America I wish to inform you that the Connecticut Agricultural Experiment Station possesses volumes 1 to 69 inclusive of this journal (1811-1833)

HARRY J FISHER, New Haven, Conn

TREATMENT OF PNEUMONIA AT HOME

To the Editor —1 Kindly summarize the major steps in the treatment of pneumonia as it may be carried out in the home in the absence of expert nursing care 2 Can the assistance of a laboratory be dispensed with? 3 Please include a few remarks on the status of antiserums 4 Do you approve of the use of oxygen from small tanks with which it can be administered by the funnel method? 5 I believe that most of us in the country are still using largely expectant treatment and wish to know if we are justified Please omit name

M D Idaho

ANSWER —1 Patients suffering from pneumonia may be satisfactorily cared for in the home without trained nurses if the physician carefully directs the nursing and is alert in interpreting and treating symptoms To some extent the outcome will depend on the nursing When the diagnosis of pneumonia is made, the patient should be put to bed in a well ventilated room and spared any unnecessary exertion or annoyance He should not leave his bed for any purpose until the temperature and pulse are normal for a week No purgative should be used The bowels may be emptied with a mild laxative suppositories, or an enema in bed The diet should be nutritious, salty, and as generous as the patient desires

Excessive coughing should be calmed with codeine sulphate, 0.03 Gm (one-half grain) Pleuritic pain may be relieved by strapping with adhesive plaster, by codeine, 0.03 Gm, or by a small single dose of morphine sulphate, from 0.008 to 0.016 Gm (one-eighth to one-fourth grain), never more Headache should be treated with amidopyrine, 0.3 Gm (5 grains), and restlessness and insomnia by one of the rapidly destroyed barbiturates, such as dial-Ciba, 0.2 Gm (3 grains), or sodium amylal 0.2 Gm If ineffectual, the dose may be repeated in one hour

Other menacing symptoms such as cyanosis distention delirium and pulmonary edema occur most frequently in cases in

which there is a bacteremia or anoxemia, and usually late in the disease. For a bacteremia there is no available remedy other than type-specific serum. A much larger amount of serum is required to treat patients later in the disease, or those suffering from a bacteremia than if serum is given early and before the bacteremia develops.

Cyanosis can be met only by increasing the gradient between the alveolar and the blood oxygen by inhalation of oxygen with a nasal or tracheal catheter or well ventilated tent.

Intestinal or colonic distention is met either with enemata, a rectal tube turpentine stipes or doses of ampoules of pitresin 1 cc. every hour for three doses. Gastric distention may be relieved by cruminals as peppermint or by stomach tubing with a Levine tube.

Delirium requires large doses of the barbiturates with or without tribrom ethanol (by rectum) 60 mg. per kilogram, to induce sleep (Bullowa, J. G. M. *Internat. Clin. North America* 17:103 [July] 1933).

Pulmonary edema may be met by the intravenous injection of dextrose 50 per cent (100 cc.) and insulin (20 units) subcutaneously. This may be repeated in three hours.

The complications such as empyema must be promptly recognized and treated.

2. Pneumonia patients cannot be satisfactorily treated without some laboratory assistance. In many states this is provided by central laboratories to which sputum is sent. In almost every community a compound microscope is available and with it the laboratory can be improvised. Special rabbit typing serum for pneumococci of types I, II and III and for some of the other types is prepared in capillary tubes by at least two manufacturers—Lederle Laboratories and Parke Davis & Company. With these a Neufeld test (Sabín, A. B. *THE JOURNAL* May 20, 1933 p. 1584) may be done when there is sputum and the type specific serum available and the type determined directly thus. This may be done by the physician who has familiarized himself with the technique, or by a technician. If a laboratory is available, the Sabín technique (Sabín, A. B. *Proc. Soc. Exper. Biol. & Med.* 26:492, 1929) should be employed with the peritoneal exudate of a mouse injected with sputum and blood cultures taken. A failure to find pneumococci of types I, II or III in the sputum does not exclude the pneumococcus as the cause of the disease but finding a type is very strong presumptive evidence that it is responsible for the pneumonia. The report of type or group IV should not be accepted as evidence that the patient is not suffering from one of these types (I, II or III) or from some other specific type. The report usually means that the laboratory has not found a precipitation or agglutination reaction with serum for pneumococci of types I, II or III. Type I, II or III pneumococci may be present but not in sufficient numbers to give the test, or there may be inhibiting substances.

3. The favorable results of serum treatment in pneumonia due to pneumococci of types I and II have been amply shown by Cole (*THE JOURNAL* Sept. 7, 1929 p. 741), Park and Cooper (*THE JOURNAL*, April 28, 1928 p. 1349), Bullowa (*New York State J. Med.* 33:13 [Jan. 1] 1933), Cecil and Suthill (*THE JOURNAL* Dec. 22, 1928 p. 2035), Cecil and Plummer (*THE JOURNAL*, March 5, 1932 p. 779) and Heffron and Anderson (*THE JOURNAL* Oct. 21, 1933 p. 1286). In Bullowa's statistics in alternately treated cases at Harlem Hospital, the mortality in serum treated cases was reduced to 15 per cent of all cases of type I admitted to the service, as contrasted with 30 per cent in the controls. In the state-wide Massachusetts series, in which some of the cases were treated at home it was reduced more than half than in the controls, to 10.6 per cent. The treatment with type II serum is definitely helpful though the results are not as striking as with type I, it prevents invasion of the blood by pneumococci. It is even more important than with type I that the serum be given early and in large amounts. Bullowa has indicated the value of specific serum in type VII (Cooper) and type VIII (Cooper). Serum for types I and II and for type VII is commercially available. Several other types are being experimentally studied but reports of the results have not been published.

Since approximately 50 per cent of all cases of lobar pneumonia are due to pneumococci of type I and type II, duovalent serum for type I and type II may be administered in advance of typing (at least 20,000 units twice). In cases known to be due to pneumococcus type I the doses should be repeated until clinical improvement is manifest, as evidenced by a fall in the pulse rate. For type I about 100,000 units is required for moderately severe nonbacteremic cases and 200,000 units for bacteremic cases. This should be given in twenty-four hours. For type II much larger doses are required.

Though it is desirable that cases be treated before the fourth day, serum may be effective at any time, even late in the disease, and it should not be withheld because of the length of time the patient has been ill.

4. The administration of oxygen from small tanks with a funnel is not approved. The funnel must be held close to the face, which procedure interferes with escape of carbon dioxide and of moisture, or at such a distance as prevents an adequate increase of the concentration of oxygen in the air breathed. A preferred method is with an inhaler (Connel, Sanford or Bullowa) which delivers moistened oxygen just inside the nares, or with a catheter or catheters leading to the nasopharynx (Bullowa, J. G. M. *Internat. Clin.* 4:262 [Dec.] 1931).

The small tanks contain insufficient oxygen for continuous treatment. They contain either 11 cubic feet (100 gallons) or 17 cubic feet (130 gallons) of oxygen (7½ gallons = 1 cubic foot) and cost about half the price of large tanks containing 220 cubic feet (more than twenty times as much oxygen). The small tanks have the further disadvantage of usually having neither a gage to indicate the rate of flow nor one to show the cylinder pressure. The latter tell how much oxygen is in the tank. Large tanks of oxygen containing 220 cubic feet are available wherever there is a welder (which is in nearly every garage in almost any community).

There is absolutely no difference between industrial and 'medical' oxygen. Some salesmen attempt to make physicians believe there is.

With large tanks (220 cubic feet) at 2,200 pounds pressure a pressure regulator and a flow gage are necessary. The variable orifice meter or float gage, calibrated for liters per minute is the preferred form. In the absence of such a clinical regulator one may improvise with the welding equipment of the garage. The pressure regulators of welders are said to be

Improvised clinical regulator for use with industrial oxygen cylinder. A delivery gage and B cylinder gage on C industrial oxygen cylinder (220 cubic feet). D orifice in welding tip or brass slug. E wash bottle. F nasal inhaler (Bullowa type).

accurate to 3 per cent and they begin to register at 2 pounds pressure. The flow rates of gases at a given pressure through a given orifice are well known.

An orifice meter may be improvised suitable for clinical use, by placing a metal disk with a suitable drill hole in series with the welding regulator as shown in the accompanying diagram. The amount of gas passed in liters per minute is approximately half the number of cubic feet per hour for the given pressure. An Airco No. 1 welding tip may be used (No. 68 drill), or that of some other manufacturer with the same size opening.

The table gives the amount of gas, in cubic feet per hour, passing common drill sizes at the pounds pressure indicated. The figures divided by 2 give liters per minute.

The gas should be passed through a water bottle to prevent drying of the nasal mucous membrane. At 4 liters per minute, a large tank of oxygen provides enough oxygen for continuous inhalation for more than twenty-four hours, at a cost of little more than \$5 for oxygen.

Oxygen should be given continuously if indicated. It is good practice not to wait until there is marked cyanosis before

administering oxygen The oxygen gradient should be increased before the mechanism that prevents cyanosis is exhausted At Harlem Hospital, oxygen by nasal inhaler is given, in pneumonia, when the normal respiratory rate is doubled, or 36 per minute, or the pulse reaches 120 or if there is cyanosis of the nail beds (*Bullowa Internat Clin* 4 262 [Dec] 1931)

The intermittent administration of oxygen with a funnel was born of economizing with the gas in the days of small and expensive cylinders before liquefaction or electrolytic oxygen was made, and it has no place in the medicine of today Relatively inexpensive oxygen suitable for inhalation is in almost every repair garage, and the apparatus for increasing the concentration of the pharyngeal oxygen by at least 50 per cent can be improvised almost anywhere from the welder's equipment The physician or hospital may have a clinical regulator available for an emergency

Flow in Cubic Feet Per Hour

Pressure	Drill No 60	Drill No 65	Drill No 70
1	9.0	7.0	4.4
2	12.8	9.8	6.2
3	15.7	12.0	7.6
4	18.0	13.8	8.7
5	20.3	15.4	9.8
6	22.1	16.8	10.7
7	23.8	18.2	11.6
8	25.6	19.4	12.3
9	27.0	20.6	13.1
10	28.4	21.6	13.8

5 Unfortunately, the physician treating pneumonia must treat "expectantly" many patients suffering from pneumonias not due to pneumococci or due to pneumococci of types for which an effective specific curative serum is not available A physician is not justified in failing to treat aggressively with serum a disease (pneumonia due to pneumococcus type I) in which the serum has been shown by many observers, with ample controls to cut the death rate in half and thus save from ten to fifteen lives per hundred patients Prompt administration of type I serum shortens the illness and prevents bacteremia and other complications In this country, physicians are not justified if they fail to treat diphtheria with antitoxin The results from the use of serum in type I pneumonia if it is used early and in sufficient quantity, are almost as satisfactory as those with diphtheria antitoxin when used early in diphtheria

The aggressive treatment of many acute abdominal conditions has displaced the so called expectant, or laissez-faire, treatment even in the country The aggressive treatment of pneumonia with serum and oxygen requires skill and devotion A significant country-wide reduction in the mortality from pneumonia will appear when the physicians of the country employ efficiently, in the treatment of the pneumonias for which serum is or becomes available, the newer methods, especially serum and oxygen

RHINITIS AND SINUSITIS

To the Editor—A man aged 55 is suffering from a chronic catarrhal condition of the rhinopharyngeal region There is continuous hacking of the throat for the removal of a mucous discharge of a thick sticky quality There is a wheezing respiration with many coarse rales heard over the bronchi during any accentuation of the condition by an acute cold There were also at a considerable period at the beginning of treatment many rales in the right lower lobe The patient had a discharge from the ear from the age of 18 to 26 years at intervals which cleared up with the removal of the tonsils The chronic catarrhal condition together with a susceptibility to colds increased gradually in intensity from the age of 26 years Two years ago after examination in a clinic of high repute a nasal operation was done for removal of obstruction and establishment of drainage but without much benefit Beginning in March 1933 when the patient came under my care I have done sinus lavage administered some iodine intravenously and given a long series of injections of vaccine made up of a polyvalent entolysate of the rhinopharyngeal organisms All seems to have resulted in considerable benefit Please give suggestions as to the care of patient Please omit name and address

M D Wisconsin

ANSWER—Before the hacking and postnasal dropping are dismissed as manifestations of a catarrhal condition it is necessary to rule out by every means at one's disposal the presence of a suppurative accessory nasal sinusitis If and when it is definitely proved that the secretion in the pharynx does not come from the sinuses, one may diagnose a catarrhal rhinopharyngitis The chronic bronchitis present could be secondary to a suppurative sinusitis In this event improvement in the nasal condition might ameliorate the chest complaint In the absence of pus in the nose the bronchitis is in all likelihood a concomitant but unrelated disease

In addition to the local nose treatment already instituted one could consider removal of the patient for a time to a warm

dry climate such as is found in Arizona or New Mexico This would offer a good prognosis if the patient now dwells in an unfavorable locality as in a northern industrial city situated on a large body of water and with a variable temperature and a dust and smoke laden atmosphere

SEXUAL INFANTILISM—DYSTROPHIA ADIPOSEGENITALIS

To the Editor—Recently a case of hypopituitarism came under my care The patient a boy aged 15 years, weighs 168 pounds (76 kg) and has definite sexual infantilism The basal metabolic rate is -3 I should like to know the present status of glandular therapy in this disorder An outline of the regimen in such a case would be appreciated

O O BENSON, JR MD, March Field Calif

ANSWER—It may be assumed that the condition from which this boy suffers is a dystrophia adiposogenitalis This is a condition of obesity associated with sexual infantilism The opinion is divided as to whether the disorder is due to a pituitary deficiency or to some disturbance in the hypothalamic region of the brain

There is considerable difference of opinion as to the result of pituitary treatment Clinicians of considerable experience have not succeeded in remedying the condition with this line of treatment

On the other hand, more enthusiastic physicians maintain that larger doses of pituitary preparations, continued over a longer period, will cause improvement in these patients It is obvious that, if there is a tumor or pressure on the hypothalamus, glandular treatment will be of no avail

In THE JOURNAL October 14, Brosius and Schaffer reported the successful treatment of a case of complete aspermia with bilateral testicular atrophy by injections into the glutei of a preparation of anterior pituitary-like principle from pregnancy urine This report carries with it a suggestion of the future possibilities in the treatment of sexual infantilism

DERMATITIS FROM CAUSTIC SODA

To the Editor—One of my patients three or four years ago contracted eczema brought on by exposure to caustic soda and since then has been afflicted with it almost continuously The eruption has been generalized uncommonly severe and difficult to cure Could exposure on another occasion to the fumes of caustic soda be regarded as a causative factor in a further outbreak? The outbreak occurred on a very hot July day this year and was coincident or appeared shortly after the dumping of caustic soda into a sink Please omit name and address

M D Massachusetts

ANSWER—The action of various skin irritants appears to be such that a foreign protein is produced on or within the skin with the further result that the affected person becomes sensitized Thereafter even limited exposure to the same irritant may be followed by severe skin damage which is chiefly anaphylactic in character It cannot be said that the body is specifically sensitized to the offending chemical agent, but it is sensitized to the peculiar protein produced when that irritant is in contact with the skin It is believed that the dust of caustic soda—or the fumes originating from such caustic soda brought in contact with water—may either bring about a new chemical burn of the skin or provoke a dermatitis related to a previous outbreak from the same cause months or years earlier

CALCIUM IN BLOOD SERUM

To the Editor—The remark has been made that blood serum calcium determinations are valueless since quantitative calcium analysis of blood serum cannot be done accurately Is there any justification for this statement?

G D GUILBERT MD Tucson Ariz

ANSWER—The statement that blood serum calcium determinations are valueless is incorrect The quantitative determination of serum calcium, if properly carried out according to the instructions of Clark and Collip should reduce errors to 2 per cent or less The method of Clark and Collip is described in Kolmer and Boerner's Approved Laboratory Technic, New York D Appleton & Co, 1931

Blood calcium determinations are indicated as an aid to diagnosis when osteomalacia, polycystic bone disease, which is often associated with a tumor of the parathyroid, rickets, parathyroid disorders or infantile tetany is suspected It is especially important in following the results of treatment with parathyroid extract Excessive doses of viosterol may cause an increase in the calcium level of the blood

The normal blood serum calcium is about 9 to 12 mg in 100 cc of serum Osgood and Haskins place the normal figures for serum at 9 to 14 mg and for plasma at 10 to 15 mg

ENEMAS OF METAPHEN AND GLYCERIN IN COLITIS

To the Editor—A woman aged 47 married with five children weighing 115 pounds (52 kg.) white well educated of upper class society, energetic and not especially nervous presents a puzzling reaction to some medication I recently gave her. At 19 she had a nervous collapse (?) followed very soon by the syndrome of mucous colitis. Rest in bed cleared that condition for a time. Several years later some sort of ulcers developed in the rectum. During her pregnancies she seemed entirely well. Five years ago a diagnosis of visceroptosis was made and rest in bed and corseting seemed to correct the condition. There have been times when the ulcers became bothersome and she had them treated by cautery or some such method. I saw her first about six weeks ago when she complained of loose watery stools usually involuntary in the morning with the constant appearance of small amounts of bright red blood similar to ulcer symptoms. She maintains that the stools are a straw colored water and only occasionally contain any formed matter of size. Three weeks ago I prescribed metaphen 1 500 and glycerin equal parts. The patient had a slight nausea but the bleeding and water stools disappeared, and she had one or two perfectly formed normal stools each day with no involuntary tendency. Each time the metaphen was stopped constipation set in and in a day or two the water stools reappeared with blood. Laboratory examination gives essentially negative results and there does not seem to be any suggestion of malignancy. I am especially interested in the peculiar reaction to the metaphen and glycerin. Is the regulation of the bowels due to the glycerin and if so is there any contraindication to the indefinite continuance in the use of the mixture of glycerin alone? The symptoms reappear so promptly when she stops it that the patient does not feel like discontinuing it. I would be glad to have any other suggestions. Can tonic doses of ultra violet radiation be counted on to help this condition? Please omit name.

M D, Pennsylvania

ANSWER—Glycerin injected into the rectum is a reliable evacuant and if the mixture of metaphen solution and glycerin equal amounts was injected into the rectum, one would not hesitate to ascribe the result to the glycerin. Whether this is correct could be easily tested for by employing either of the ingredients alone. If the effect is due to the glycerin there is a possibility that in time regularity of bowel movement may be secured by progressive dilution of glycerin as glycerin enemas have a tendency to leave an irritability of the rectal mucosa as an after-effect. The patient's symptoms suggest a possibility of ulcerative colitis, the treatment of which demands thoroughgoing roentgen and bacteriologic study to determine the best course to pursue. Ultraviolet rays are not likely to be of much value in this condition.

SCOTOMA SCINTILLANS AND SYNCHESIS SCINTILLANS

To the Editor—I have a patient who has scotoma scintillans in both eyes to such an extent that it troubles her greatly. She is a teacher and it is unusually important that her vision remain good. In searching through the literature I find one reference in which scotoma scintillans occurred in an allergic individual who also was having other eye disturbances. I have found that scotoma scintillans depends on infection. I am wondering if you can help me out by any further data on the literature.

ORVILLE HARRY BROWN M D Phoenix Ariz

ANSWER—The question is probably misstated. If scotoma scintillans is meant there need be no fear for the ocular future for that symptom is merely one of the prodromals of an attack of migraine. But if synthesis scintillans is meant (and the question would seem to indicate that) a different condition is involved. For a complete digest of the literature the inquirer is referred to the Graefes-Saemisch Handbuch der gesamten Augenheilkunde ed 11, vol V chapter VIa by H. Lauber, p 107. This contains the literature up to 1922. From then to date, the inquirer is referred to the Kurzes Handbuch der Ophthalmologie, vol V, p 346, Synthesis Scintillans by A. Jess.

TREATMENT OF POTTS DISEASE

To the Editor—A man aged 29 has had Pott's disease since 1923. The Albee operation was performed on him in 1928 with good results until a few months ago when he began to feel pain and fatigue in the back. At inspection a marked kyphosis and right scoliosis were present. Roentgenograms showed complete destruction of the body of the eleventh thoracic vertebra while the bodies of the tenth and twelfth vertebrae were partly destroyed. The anterior picture revealed an old calcified abscess. A cure on the Bradford frame was recommended. I would like your appreciation of the method for this case. Can it be carried on in the patient's home? If so would you give me sufficient instructions regarding the structure of such a frame to enable me to have one made for my patient?

A R COTE M D Brownsburg Que

ANSWER—The roentgen examination must be checked with the results of former roentgen examinations in order to determine the progress or retrogression.

Home treatment may be successful up to a certain point. The Bradford frame treatment may be carried out at home if hospital nursing is carried out. This is comparatively simple and can be taught to any intelligent person.

The Bradford frame is a frame usually made of three eighths inch gaspipe bent into a rectangular form. An elbow is placed at each of the four angles. The width of the frame is the distance between the two scapulae at the point of the glenoid. The length should be about 8 inches longer than the height of the patient. The curve of the frame depends on the individual patient. After the frame is bent, it is covered with two or three sections of canvas. This canvas should have brass eyelets into which heavy lacings are passed, on the under surface of the frame, so that the patient is suspended on a canvas frame.

The roentgenograms should be checked and rechecked with the idea of determining whether another operation of the Albee or Hibbs type (or some combination of the two) should be prescribed either immediately or after a period of one or two months of Bradford frame treatment.

USE OF MENTHOL INTERNALLY

To the Editor—I noticed the following article in a small paper sent out by a drug company: Zur abortiven Grippebehandlung (Abortive Treatment of Grip) by Friederike Schnapek (Wien klin Wchnschr Sept 8 1933). Grip in uncomplicated cases may be aborted by the administration of 0.5 Gm of menthol within a space of two hours. This should be done at an early stage. In from eighteen to twenty-four hours the patient is fever free. Cough and nasal affections are avoided by this treatment and the physical equilibrium is restored. None of the late sequelae of grip follow. The menthol may be given in any shape or form with the same effect. I tried to make up a prescription containing 8 grains of menthol using alcohol to dissolve the menthol and added syrup to 1 ounce. About one-fourth teaspoonful of this nearly choked me the fumes coming out of my nose and eyes. How could 8 grains of menthol be prescribed for internal use other than in capsules?

DR VERA RITCHIE M D Harrisburg Pa

ANSWER—The author prescribed the menthol in a liberal quantity of olive oil and for patients who objected to drinking the oil he prescribed the menthol dissolved in a small quantity of oil in capsules. Such a prescription might be written as follows:

R Menthol	0.5 Gm
Olive oil	4.0 cc.
Divide into 12 capsules	
Label: One every ten minutes until all are taken	

It would hardly be desirable to make it more concentrated, as even this strength is rather fiery. Incorporating the menthol in a wax mass formed by beeswax 1 part castor oil 3 parts (as suggested by N. S. Davis) might make it possible to reduce the quantity of the diluent and the number of capsules. One would hardly want to inflict the powdered menthol on a patient's stomach. Of course there is no good evidence that menthol used in this way actually aborts a cold.

DEATH FROM FRIGHT

To the Editor—This question has been presented to me several times. Can a man die from fright? alone without any history of actual physical injury. I should like to know what available evidence there is in favor of and against together with references for this question. If this question is answered in THE JOURNAL please omit my name.

M D Chicago

ANSWER—The question was referred to an eminent authority in legal medicine. He says that in a large experience of over forty years of actual postmortem observation abroad and in this country he has not encountered a single case of death from fright in a person of sound physical condition. Persons afflicted with serious valvular lesions or with marked coronary sclerosis and interstitial myocarditis may die suddenly after fright especially if aged. Sudden death after plunging into cold water may be considered an example of death following fright with shock.

References on this subject may be found in any of the large textbooks on medicolegal medicine—Haberda and others.

ACROPARESTHESIA

To the Editor—Will you please tell me the treatment of acroparesthesia? I have a typical case and cannot find much in the literature on the subject. Phenobarbital 1½ grains (1 Gm.) has only slight effect on the pain and the patient is losing much sleep. Please omit name.

M D Kentucky

ANSWER—The term acroparesthesia merely implies paresthesia of distal parts. The latter occurs in a great many conditions notably combined cord degeneration, tabes, multiple neuritis and arteriosclerosis. The question no doubt relates to the ill defined vasomotor or trophic neurosis often referred to as acroparesthesia and paraded as a clinical entity, which

it is not. One type is described as occurring in young persons another and more common one at the menopause or later. The only observer who makes claims for a curative treatment is J. Borak (*Endocrinologic* 5:9 [Oct] 1929), who describes excellent results from roentgen treatment directed at the hypophysis. Vasodilators or vasoconstrictors are indicated when there is objective evidence of such indication. Ovarian hormones may be tried in menopause cases associated with other signs of menopausal neurosis. Quinine, strychnine, arsenic, iron, phosphorus and ergotone have been recommended as has the faradic brush according to Oppenheim it is well for such patients to keep their fingers out of water.

EARLY INVESTIGATIONS OF ANTRUM OF HIGHMORE

To the Editor—I wish to know the name of the physician who first described a suppurative antrum of Highmore and the date of the discovery. The following may facilitate the finding of the name. He was an English physician who suffered from a foul breath which caused him to lose his practice. He went to Egypt for his health where he observed the dripping of the ill smelling pus from his nose as he leaned over. Please omit name.

M D New York

ANSWER—According to Wright, it was Nathaniel Highmore who in 1651 described the sinus named after him. He gave anatomic data with illustrations and mentions a case of suppuration on an old woman who had bad teeth. In 1675 Velpeau quotes Molinetti, who entered the antrum of Highmore in a patient suffering from severe pain due to suppuration in this cavity, with a trephine through a crucial incision in the tissues of the cheek. Morgagni intimated that Jean Henry Meibomius prior to 1655 was the first to enter the maxillary sinus by way of the alveolar process. The credit is generally given to William Cowper, however, whose publication appeared in 1717. He used a suitable instrument, entering the antrum through a tooth socket from which the tooth had been extracted for this purpose. Following the entrance of the instrument into the antrum, irrigations were practiced by him. Following Cowper, there were others who suggested opening the sinus in a number of ways.

ANKYLOSIS OF KNEE

To the Editor—Will you give me the best treatment for ankylosis of the knee joint of about three months standing caused from a fracture below the knee and the cast being left on too long. I have not been able to find a book that gives anything on it. Please omit name.

M D Illinois

ANSWER—It is desirable to know whether the ankylosis is fibrous or osseous. One should know the exact nature of the fracture, stating whether it extended into the knee joint. It should state whether the knee is flexed or extended. A plaster cast should not be discredited or blamed for more than its share.

Joint irregularity and the integrity of the tibial plateau are important considerations. Roentgen reports should be given.

The various factors under treatment to be mentioned are wedged casts, leg traction below the knee, the use of the Zander apparatus, physical therapy including radiant heat, massage and gentle manipulation. If these measures are unsuccessful one would recommend very gentle manipulation under gas induction followed by ether. This manipulation may have to be repeated and should be followed by physical therapeutic measures.

EPILEPSY

To the Editor—An Irish American woman aged 33 single has had for the past nine months typical attacks of epilepsy at first every month at the beginning of her period and then every two weeks. The attacks appeared only at night and there were as many as three to four during one night. After four months of a ketogenic diet increasing from number 2 to number 4 the attacks now come only the night before the period appears and there is only one convulsion. Does it not appear that the pituitary is at fault and would not hypodermic pituitary medication of some kind help? Roentgenograms were taken of the patient's head and no old fracture or abnormality of the pituitary was noted. Please omit name.

M D Massachusetts

ANSWER—The first appearance of epileptic seizures at the age of 33 always suggests the possible presence of an organic brain lesion and indicates the necessity for a particularly careful neurologic examination. At the menstrual period there is normally a temporary alteration in the chemistry of the blood, a fact that may render the brain more liable to the explosive discharges of epileptic nature, provided a cause for the seizures is present. The suggestion of pituitary etiology from the facts given in this case would be mere speculation.

EFFECTS OF ACTIVE MATERIALS FROM LETTUCE

To the Editor—In popular articles I have repeatedly seen the statement that there is present in lettuce some sleep-producing alkaloid but I have not been able to find any reference to it in any scientific work. May I ask you whether there is any such alkaloid present in lettuce and if so what alkaloid it is? Is it ever found in sufficiently large quantities in lettuce to produce lethargy or sleep in those eating lettuce? Any references you can give me to scientific literature will also be most welcome. Kindly omit name.

M D California

ANSWER—There is no such alkaloid in lettuce. *Lactuca virosa* the wild lettuce contains a milk juice, which when inspissated is known as lactucarium. This has been called "lettuce opium" and credited with sedative effects. As it does not contain any alkaloid and is not narcotic the term lettuce "opium" is applicable only if the word is used in its etymologic sense, meaning "juice." Lactucarium was introduced by Dr. Cove of Philadelphia (*Tr. Am. Phil. Soc.* 4, 1799 cited in Lloyd's "Origin and History of Vegetable Drugs," 1921) but because of unreliability of its effects, its use has been abandoned.

FIRST CATHETERIZATION OF EUSTACHIAN TUBE

To the Editor—Would you be kind enough to advise me as to who was the first to introduce the eustachian catheter method of middle ear inflation?

BENJAMIN BRONSON M.D., Westfield Mass.

ANSWER—The histories are unanimous in assigning credit to Guyot as the first to catheterize and inflate the eustachian tube. His report was made in 1724 (*Histoire de l'Academie royale des sciences*, 1724 p. 37). Guyot successfully passed a catheter through the oral cavity, under the soft palate into the mouth of the eustachian tube. In 1741, Archibald Cleland, an English military surgeon first reported passing a catheter into the eustachian tube by way of the nose.

The subject is referred to by

Garrison *History of Medicine* 1929

Politzer *Geschichte der Ohrenheilkunde* Stuttgart 1907, vol. 1

GROWTH OF DIABETIC CHILD

To the Editor—A boy aged 16 weighing 116 pounds (52.6 Kg.) and 51 inches (129.5 cm.) tall has had diabetes since he was 5 years of age and has been on insulin for several years. His parents are apprehensive about his size. In your opinion would there be anything that might increase his growth? Please omit name.

M D Nebraska

ANSWER—Growth can continue even up to 26 years of age unless the epiphyses have closed. Control of the diabetes with sufficient insulin, exercise and a diet of carbohydrate 140-175 Gm., protein 90-100 Gm. and fat 90-110 Gm. will almost certainly produce growth. Thyroid 0.065 Gm. after each meal and pituitary whole gland, 0.13 Gm. three times a day, may help, but any patient receiving glandular treatment should be examined at least every three months.

MOTTLED ENAMEL

To the Editor—Several persons who have read the story about the mottled enamel situation in the West have written to inquire what is the objection to mottled enamel. Is there any objection to it aside from the fact that it is deleterious to appearance?

G EDWARD PENDRAI New York

ANSWER—There is apparently no other objection to mottled teeth than the one mentioned, though in many cases the discoloration is extremely conspicuous. Dental decay is certainly not more common in mottled teeth; indeed, both McKay and G. V. Black are of the opinion that individuals with this condition have relatively little decay (*J. A. Dental A.* 15:1429). No other abnormal changes of the mouth or teeth have been associated with this developmental fault.

USE OF ACIDOPHILUS CULTURES

To the Editor—I should like some information on the acidophilus treatment for constipation in which bacteria are believed to be the cause. Are the fresh cultures the only satisfactory method of using the preparation? If so where are they obtained and how prepared? Are there any proved vaccines on the market for this purpose? Please omit name.

M D Minnesota

ANSWER—*Bacillus acidophilus* is not actively laxative. Lactose taken in liberal quantities may become so through the action of *Bacillus acidophilus*. Buttermilk is a good and inexpensive method of lactic acid bacillus therapy. When this cannot be used for some reason or other, any one of the various cultures on the market, which must be relatively fresh, may be used. N. N. R. lists quite a number of them. Vaccines (for subcutaneous injection) are not employed.

INTRAVENOUS INJECTION OF DEXTROSE SOLUTION
To the Editor—Forty eight hours after operation a patient having lost considerable blood what amount of 5 per cent dextrose can be given intravenously with safety, the patient weighing 140 pounds (63.5 Kg)? What are the symptoms produced by too large an amount? Will a liter given rapidly produce untoward symptoms and what are they usually?
H D DIESSNER, M D Minneapolis

ANSWER—It is the rate of injection rather than the quantity that is of importance. The syndrome of too rapid injection, for which the term "speed shock" has been advocated, consists of a fall in blood pressure, respiratory irregularity and dyspnea, salivation, vomiting, diarrhea, muscle weakness, muscle spasm and impaired coagulability of the blood. Even death may result. A rate of from 2 to 3 cc per minute (intravenous drip) is considered safe.

EARLY SITTING AND STANDING OF INFANT
To the Editor—Is there any foundation for the common belief that early standing causes bow legs and that early sitting injures the infant back? My 5 months old infant likes nothing better than to sit unsupported on the bed remaining sitting from one to two minutes. She shows no signs of discomfort when she falls but immediately tries to raise her self up. She also seems to enjoy standing when supported. I believe she has no signs of rickets. Please omit name.
M D New York

ANSWER—There is foundation for the belief mentioned. If the infant can maintain good posture while sitting unsupported and standing with support, it should be encouraged frequently, but for short periods.

ADMINISTRATION OF IRON TO CHILDREN
To the Editor—Please advise me the best way of administering large doses of iron to children.
ABRAHAM TRUMPER M D, Montgomery Ala

ANSWER—Iron and ammonium citrate may be dissolved in syrup of orange flowers, as in the following:
If Iron and ammonium citrate 10 Gm
Syrup of orange flowers to make 120 cc
M Label Teaspoonful in water three times a day after meals

COCAINE AND ANTISEPTIC
To the Editor—Can you tell me the effect of cocaine in 5 per cent solution on micro-organisms? I have frequently thought in spraying the nasal mucosa preliminary to applying antiseptics for acute infections that the cocaine perhaps in itself was sufficient to destroy organisms. Please omit my name in your reply.
M D New York

ANSWER—Cocaine is not antiseptic. Indeed, its solutions require sterilization or preservation by means of bacteriostatic agents.

VENESECTION IN CEREBRAL HEMORRHAGE
To the Editor—What about bleeding as a treatment for cerebral hemorrhage?
R A HILLS, M D Russell Iowa

ANSWER—There is considerable difference of opinion just as there is concerning lumbar puncture in spontaneous and traumatic subarachnoid hemorrhage. Since there is often difficulty in distinguishing between cerebral hemorrhage and thrombosis, venesection should not be thought of unless a full pulse, red face and other signs point conclusively to hemorrhage. With the diagnosis virtually assured, such experienced clinicians as Oppenheim, Bing and Dana recommend venesection.

DIAGNOSIS OF MASTURBATION
To the Editor—Are there any infallible easily recognizable stigmas of the sex organs (both sexes) due to masturbation? I have read many descriptions of such marks and signs which I have known to be absent in chronic habitues. I am connected with two institutions in which this question often arises. Kindly give me your opinion. Please omit name.
M D Pennsylvania

ANSWER—There is absolutely no sign by which one can detect the presence of masturbation in a person. Many of these sufferers imagine that any one seeing them can immediately know that they practice masturbation, but this is not so.

DEAFNESS AFTER SKULL FRACTURE
To the Editor—Please tell me what length of time should elapse following a fracture of the skull involving the eighth nerve in which there is total deafness before one can assume that the deafness is total and irreparable.
T C KERNS M D Durham N C

ANSWER—A skull fracture producing total deafness has injured the eighth nerve, the cochlea or both these structures. The deafness as a rule is present at once, is usually complete and only rarely is there recovery.

Nevada November Report

Dr Edward E Hamer secretary Nevada State Board of Medical Examiners, reports the written examination held in Carson City, Nov 6, 1933. The examination covered 11 subjects and included 110 questions. An average of 75 per cent was required to pass. Two candidates were examined, 1 of whom passed and 1 failed. Four physicians were licensed by reciprocity. The following schools were represented:

School	PASSED	Year	Per
		Grad	Cent
St Louis University School of Medicine	(1933)	86	6
School	FAILED	Year	Per
		Grad	Cent
Hahnemann Med College and Hospital of Philadelphia	(1902)	59	1

Minnesota October Report

Dr E J Engberg, secretary, Minnesota State Board of Medical Examiners, reports the oral written and practical examination held in Minneapolis, Oct 17-19 1933. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Forty one candidates were examined, 40 of whom passed and 1 failed. Five physicians were licensed by reciprocity and 2 by endorsement. The following schools were represented:

Michigan June Examination at Ann Arbor

Dr J Earl McIntyre, secretary, Michigan State Board of Registration in Medicine, reports the written examination held in Ann Arbor, June 7-8, 1933. The examination covered 9 subjects and included 60 questions. An average of 75 per cent was required to pass. One hundred and twenty-six candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year	Per

Book Notices

Surgical Anatomy By Grant Massie M B M S F R C S Assistant Surgeon (City Hospital) Second edition Cloth Price \$6 1p 458 with 147 illustrations Philadelphia Lea & Febiger 1933

In order to help in the remembrance of anatomic facts, the author has correlated them with their clinical application. The old nomenclature is retained but the new is included. He considers the various regions of the body, taking up their characteristic anatomic points along with their application or importance. These regions are well described and include the female and male pelvis. The newer material includes injuries of the carpus, infections of the hand, the surgical approach to some long bones, and the autonomic nervous system. The section on the sympathetic nervous system is preeminently clear and concise with a correlation of the anatomic facts to their surgical application. The illustrations, while not particularly numerous for this type of work, are unusually well chosen. Their value in many instances is increased by the artist through overemphasis on certain parts. This work throughout shows the original teachings of the author and the result of mature experience. For use by the advanced student or the practitioner it may be considered an excellent textbook on surgical anatomy.

Die Differentialdiagnose der Baucherkrankungen Eine neuartige Darstellung auf Grund der konstitutionellen Sensibilitätsunterschiede der klinischen und Röntgenuntersuchung. Von Dr med A Voegell. Paper Price 22 75 marks Pp 320 with 185 illustrations Stuttgart/Lipzig Hippokrates Verlag G m b H 1933

Not only perfection of various specialties but also a correlation and coordination of them are essential for real progress in medicine. A proper synthesis of observations is a condition sine qua non for a correct diagnosis. Such considerations induced the author to form a link between the internist or surgeon on the one side and the roentgenologist on the other by offering the differential diagnosis of abdominal conditions from the clinical and radiologic points of view. One is impressed with the compact, simple and understandable presentation of the subject. The author outlines proper procedures to be employed in routine examination. The first few chapters are devoted to a careful analysis of pain and functional disturbances, such as nausea vomiting, hematemesis diarrhea, constipation, occult bleeding, meteorism and jaundice. Then follows a consideration of the history of the patient with special attention to hereditary factors, also a concise description of simple chemical laboratory methods. The physical examination is outlined rather superficially and briefly. The greatest part of the book is devoted to roentgenologic observations and their correct interpretation. As the book is designed primarily for the general practitioner only a short space is allotted to description of the technic, while roentgenographic observations in various diseases of the gastro-intestinal tract are described in a comprehensive yet thorough manner. The book is full of useful diagnostic points and illustrated with a large number of well reproduced roentgenograms. It can be highly recommended to every physician who wishes to familiarize himself with the roentgenologic aspect of abdominal conditions.

Investigations into the Oscillatory Method for Determination of Systolic Blood Pressure Its Principles and Some Errors Involved in Its Use By A Eldahl Paper Pp 168 with 75 illustrations Copenhagen Levin & Munksgaard 1933

This scholarly monograph is a clear and logical exposition of the fascinating study of the various oscillatory methods now employed in the determination of the systolic arterial tension. All the known advantages and disadvantages of the various methods are thoroughly discussed and carefully controlled experimental evidence is presented to justify any and all conclusions. The author has covered this field most comprehensively and is conservative in his conclusions, nowhere does his obvious enthusiasm lead him astray from logical thought. A number of important conclusions are demonstrated and confirmed. Among the observations of greatest clinical interest are the following: 1 The indirectly measured liquid pressures measured by means of cuff and manometer are equal to the

maximum pressure existing in the vascular section concerned when the vessel is occluded. 2 The thickness of the muscular layer on the extremity is without significance to the determination. 3 The normal brachial artery has a compressing pressure of about 10 mm of mercury and thus the indirectly determined blood pressure is approximately 10 mm higher than that found on direct determination. 4 The compressing pressure of sclerosed arteries has never been found to exceed 20 mm of mercury and therefore errors due to stiffening of the arterial walls are almost negligible. The author points out that there are really two systolic pressures to be considered: one occurring when the vessel is occluded (as in ordinary sphygmomanometry), or the end pressure and one existing when the flow of blood passes unobstructed through the vessel, or the lateral pressure against the arterial walls. Clinically the former is usually determined, while the latter is physiologically more correct. The difference between the two, however, is not significant. Unfortunately the oscillatory method of determination of the arterial tension is far more satisfactory for the measurement of the systolic than of the diastolic tension. The importance and vital significance of the diastolic tension is thus greatly underemphasized in oscillatory studies. From the point of view of the pathologic physiology of disturbed arterial tension, study of the diastolic tension is of the utmost importance. The author's exposition is clear and concise. The typography and graphs are excellent.

An Introduction to Dermatology. By Richard L. Sutton, M.D., Sc.D., I.D., Professor of Diseases of the Skin, University of Kansas School of Medicine, and Richard L. Sutton, Jr., M.D., L.R.C.P., Assistant in Dermatology, University of Kansas School of Medicine. Second edition. Cloth. Price \$7. 1p 566 with 180 illustrations. St. Louis: C. V. Mosby Company, 1933.

A second edition appearing within a few months after the first should be sufficient evidence that the authors have been successful in gaging the need of a short and concise textbook in their chosen field. The purpose of this book has been to simplify dermatology for the student and practitioner by omission of much of the theoretical and controversial material that clogs the larger books. References have been omitted but all the more important specialists who have contributed to the picture of present-day dermatology will be pleased to find their names mentioned in this volume and credit given for their work. The material is of course chiefly a condensation of the senior Dr. Sutton's popular textbook, but enough skill and judgment have been used in the selection of the material to give the impress of an original work. The authors are to be congratulated on the result.

Les gaz toxiques. Physiologie, toxicologie, protection, thérapeutique. Par L. Dautrebande, professeur à la Faculté de médecine de l'Université de Liège. Paper. Price 60 francs. 1p 371 with 125 illustrations. Paris: Masson & Cie, 1933.

This engaging publication devoted to toxic gases is not entirely limited to true gases but includes comment on such substances as mercury, antimony and phosphorus, which may give rise to vapors simulating gases. The best portion is found in the 124 pages devoted to the physiology and the pathophysiology of respiration. Among others, sections are devoted to fatigue, cyanosis, the role of the carotid sinus, reflex action of irritants in relation to respiration, and Cheyne-Stokes breathing as produced by various internal and external factors. The second general division, in which individual toxic substances are described, omits many intoxicants that might well have been included. For example, the large number of volatile solvents many of which are toxic are covered in approximately one page. To this extent the value of the book may be diminished for industrial physicians in the United States confronted with problems of toxicity in connection with a far greater variety of gases and vapors than are covered in this publication. On the other hand, chapters devoted to treatment are especially helpful as similar publications in the United States have provided only meager discussions of this aspect of toxic gases. The field of usefulness of the book is widespread. Primarily of value to the industrial hygienist and industrial physician it proffers helpfulness to the general hospital staff, the pharmacologist, the physiologist and the general practitioner in industrial communities. The contents are too technical to make the

book usable by the layman interested in industrial hazards. Something would have been gained if an index had been included instead of the table of contents, which is found at the end. This book is destined to become a much used volume of reference by workers engaged in studies of intoxicants entering the body through the portal of the respiratory tract.

Atlas of Pathological Anatomy. Volume I. Compiled by E. K. Martin, M.S., J.R.C.S. Issued Under the Direction of the Editorial Committee of the British Journal of Surgery. Supplement to the British Journal of Surgery. Cloth. Price \$17. 1p 489 with illustrations. Baltimore: Williams Wood & Company, 1930.

This volume comprises the drawings published as a supplement to the *British Journal of Surgery* during the five years 1926 to 1930. The material for the atlas has been selected from the Hunterian Museum to illustrate not only the more common varieties of morbid conditions but also as far as possible the natural history of disease and the correlation of physical signs with their pathologic causes. For this reason the arrangement is chiefly clinical. Whenever possible, drawings were made from specimens removed by operation. A certain disadvantage of this principle lies in incompleteness of the resulting picture of the disease. The editors intend to continue the publication of the atlas until it includes all subjects that can profitably be illustrated by drawings of museum specimens, without attempting a reproduction of rarities and curiosities of surgical practice. The book consists of chapters devoted to bone tumors, lesions of the stomach and duodenum, breast tumors, renal conditions including neoplasms, and gall bladder diseases. Each chapter consists of a concise review of the most common lesions, followed by marvelous photographic reproductions and superb colored plates, accompanied by short histories. No illustration, however good, can take the place of the actual inspection of specimens, but the study of beautiful illustrations as presented in this volume will both stimulate and assist in such examinations. In recent years it has been the custom to rely so much on a report from a skilled histologist that the information to be gained by a naked eye inspection at the time of an operation has often been completely neglected. A publication such as this atlas should arouse in the medical fraternity a renewed interest in morbid anatomy.

Les traumatismes fermés du rachis. Par G. Michel, professeur de clinique chirurgicale. M. Mutel, professeur agrégé et R. Rousseau, chirurgien des hôpitaux à la Faculté de médecine de Nancy. Paper. Price 50 francs. Pp 330 with 83 illustrations. Paris: Masson & Cie, 1933.

Knowledge of injury to the vertebrae has changed remarkably during the last few years. Roentgenographic examination is one of the important methods employed. It is remarkable how frequently fractures of the vertebrae have been overlooked in the past. The authors discuss the anatomy and physiology of the vertebrae individually and collectively. They discuss the mechanics of the spine and the movements, describe the examination of the wounded, and discuss complications of injury to the spinal cord. They consider also fractures and dislocations of the cervical vertebrae, fractures of the thoracic and lumbar vertebrae and dislocations. There is an interesting chapter on traumatic spondylolisthesis. Fractures of various portions of the individual vertebra are described, then traumatic lesions of the intervertebral disks and finally medicolegal considerations, including camptocormia. Many of the illustrations are highly instructive.

Fisiopatología del metabolismo basal. Por Dr. Francisco Gnecco Mozo. Prólogo del Dr. Gregorio Marañón. Paper. Price 15 pesetas. Pp 164 with 20 illustrations. Madrid: Pueyo, 1933.

With the exception of the work by Castex this is the only volume of its kind in the Spanish language. It is divided into three parts. The first is concerned with methods and apparatus used for metabolism determinations. The second discusses the physiologic variations encountered in metabolism. The third deals with metabolism in certain pathologic conditions: disorders of the thyroid gland, certain types of obesity, severe diabetes mellitus, rheumatism, nephritis and respiratory infections particularly tuberculosis. An exceptionally well prepared bibliography and the author's personal observations not only make this monograph interesting reading but confirm the scientific principles underlying metabolism.

Medicolegal

Workmen's Compensation Acts Cerebral Hemorrhage an Accidental Injury Arising in the Course of Employment—The employee, while engaged in the performance of his duties in carrying on quarrying operations for the defendant company, suffered a cerebral hemorrhage, which resulted in partial paralysis. The trial court sustained an order of the compensation commission disallowing compensation and the employee appealed to the Court of Appeals of Maryland. On the morning of July 1, an intensely hot and stuffy day, the employee in the course of his work descended several times into the quarry and arranged mud caps on charges of dynamite to be exploded. After his last trip he said that he felt hot, sat down for a while and fanned himself then started toward the car, where he usually went. Shortly thereafter he was found lying on the ground. He was taken to the office of a physician and from there to his home. Nine or ten days later he was examined by two physicians, who diagnosed his injury as cerebral hemorrhage. Another physician who saw him on the day of the accident after he had been taken home, testified that the employee was partially paralyzed and unconscious. Later the employee was removed to a hospital. A hole was made in the left temporal region of his skull, a needle introduced into the skull, and the blood which had collected there partially drained. As a result of that operation and subsequent operations, the condition of the employee slowly improved. One physician attributed the injury suffered by the employee to the effect of the extreme "temperature conditions" under which he was working on one suffering from high blood pressure. He characterized the conditions as abnormal and the day as one of the "hottest he had ever experienced." Another physician attributed the injury to the extreme heat and to the inhalation of gases released by dynamite explosions. There was testimony that the employee's high blood pressure alone would not have produced the injury had he not been subjected to the extreme temperature conditions under which he worked. While, said the Court of Appeals according to the opinions of the physicians, heat was a contributing cause of the injury, the injury was not classified by them as heat prostration, heat stroke or sun stroke but as a hemiplegic cerebral hemorrhage. The word "accident," in its ordinary and usual implication is associated with ideas of trauma and involves to a degree at least elements of force, violence and surprise. But in workmen's compensation laws its meaning has been expanded to include any mischance resulting in physical injury to the bodily tissues produced by some unusual and extraordinary condition or happening in the employment. It has been interpreted to include such untoward occurrences as the rupture of an aneurysm pulmonary and cerebral hemorrhages, hernia, infection and heart dilatation arising out of some unusual or extraordinary condition in the employment, even where the injury was due in part to preexisting disease or physical abnormality in the employee. The word "accident" or "accidental" is usually considered in connection with the phrase "arising out of," and where it seems clear that the injury arose out of the employment, the tendency of the courts has been to give the word "accidental" a liberal construction in harmony with the general intent of the act so as to find the injury compensable. As a result of that policy, such injury as cerebral hemorrhage when occasioned by some unusual and extraordinary condition in the employment is by the great weight of authority held to be accidental in its nature. The conditions under which the employee worked were peculiar to the employment and not such as affected the public generally in that neighborhood. When those facts are considered in connection with the medical testimony, they furnish legally sufficient evidence to permit the inference that the employee's injury was caused by unusual and extraordinary conditions in the employment that it was accidental in its nature, and that it arose out of and in the course of the employment. The judgment of the trial court therefore, affirming the order of the industrial commission disallowing compensation was reversed and the case remanded for a new trial.—*Schemmel v T B Gatch & Sons Contracting & Bldg Co (Md)* 166 4 39

Workmen's Compensation Act Abdominal Tumor Attributed to Trauma—The employee, while using a "breast auger" in boring holes incident to coal mining, experienced a pain in his abdomen, July 22 or 23, 1931. He testified "I was putting my weight, pushing against my abdomen and something stung me like a pin stuck in there." He worked two days thereafter but was then forced to quit. He consulted the company physician early in August, 1931, who discovered a tumor mass near the umbilicus and sent the employee to a hospital. There he was operated on and the tumor removed. The industrial commissioner refused to award compensation and the employee appealed to the Supreme Court of Appeals of West Virginia. The company physician testified that when he examined the employee in August, 1931, he found a "tumor mass of the abdomen," but there was no outside evidence of any injury, and he doubted whether the disability was the result of the injury complained of. The operating physician testified that the muscles of the abdomen had evidently been traumatized by using the auger to such an extent that the employee had developed a "tumor mass" of the abdominal muscles. He testified that a pathologic analysis of the tumor disclosed a "low grade of infection of the fascia and abdominal muscles due to trauma," and in his opinion there was no question but that the tumor was caused by the trauma. There was nothing in the record said the Supreme Court of Appeals, to contradict affirmatively the clear and definite statements of the operating physician. The evidence, therefore, in the opinion of the court established the fact that the employee's disability was a result of an injury received by him in the course of his employment. The case was remanded for an award to be made in compliance with the workmen's compensation act.—*Epperson v State Compensation Comr (W Va)*, 169 S E 168

Insurance Death "from Illness or Disease of Any Kind"—The appellee was the beneficiary of a life insurance policy issued by the appellant company on the life of her husband. The policy contained a double indemnity benefit clause, which was not to apply if the insured's death resulted from physical or mental infirmity or directly or indirectly from illness or disease of any kind. An automobile, which the insured was driving, ran into a ditch. The insured was found in an unconscious condition. Stimulants were given and artificial respiration attempted by two physicians but the insured died about two hours later without having regained consciousness. An autopsy disclosed that the insured had arteriosclerosis and enlargement of the heart. Experts for the beneficiary testified that in their opinion the death of the insured had resulted from concussion of the brain caused by blows on the head. Experts for the insurance company on the other hand, testified that the death of the insured had been caused by a heart attack due to the failure of the coronary artery to supply sufficient blood to the left ventricle. The trial court gave judgment for the beneficiary and the insurance company appealed to the United States circuit court of appeals, tenth circuit. Where the matter under inquiry is one on which a witness possesses expert knowledge which will be of aid to the jury in reaching a correct solution of the issues and is therefore properly the subject of expert testimony it is no objection, said the circuit court of appeals, that the opinion elicited from the expert is on an issue or point to be decided by the jury. A medical expert, after stating the facts, or assuming the facts on which his opinion is founded in case the question is hypothetical may give his opinion as to the cause of death. The district court did not err, therefore, in admitting the testimony of the experts for the beneficiary as to the cause of death.

The district court instructed the jury that if they found that the insured experienced an attack at the time of his injury which was new or unusual with him, arising from some sudden or unexpected derangement of the system, though it produced unconsciousness, it would not be a disease or bodily infirmity within the meaning of the insurance policy and would not exempt the insurance company from liability in this action. This instruction said the circuit court of appeals, excludes from the term disease or bodily infirmity a physical condition that was either sudden or unexpected, and which manifested itself in an attack which was either new or unusual. Diseases

of the heart are frequently insidious. Many persons die from a disease of the heart without being cognizant of such infirmity. In such cases the condition is unknown and unexpected and the attack is new, yet, continued the court, it is clearly an existing physical infirmity or disease. The instruction in effect told the jury that, even though they should find that the insured had suffered a heart attack at the time of the accident, if he had not theretofore been subject to such attacks and was not aware of the condition of his coronary artery and heart then such condition would not be a bodily infirmity or disease within the meaning of the policy. The evidence showed that the insured had a serious ailment of the coronary artery and heart. Under the facts, such ailment may have rendered the insured unconscious and caused him to drive off the road and strike his head on some portion of the automobile. If such were the facts, the heart ailment was a contributing cause to his death, although the primary cause may have been concussion of the brain. Under the facts, the blows on the head may have been insufficient to have caused his death and the insured may have died from a heart attack. If such were the facts the heart ailment was the primary cause of death. The testimony showed that the insured had not theretofore suffered a heart attack and was unaware of the condition of his heart and coronary artery. Such being the facts the instruction excluded those conditions which were clearly diseases or bodily infirmities, both as a contributing cause and as a primary cause of the insured's death. The instruction was therefore erroneous and prejudicial. The judgment of the district court in favor of the beneficiary was reversed and the case remanded for a new trial.—*New York Life Ins. Co. v. Doerksen* 64 Fed. (2d) 240

Silicosis Liability of Employer in West Virginia—In the course of his employment an employee contracted silicosis and died. His widow instituted a common law suit against the employer for the alleged wrongful death of her husband. The trial court overruled a demurrer to the declaration, interposed by the employer, who appealed to the Supreme Court of Appeals of West Virginia.

The gravamen of the employer's defense was that the workmen's compensation act of West Virginia relieves subscribing employers from liability to respond in damages for the injury or death of an employee, however occurring, regardless of whether or not there is involved a compensable injury. To justify this contention, the employer referred to section 2516 of the workmen's compensation act, which reads in part

Any employer subject to this chapter who shall elect to pay into the workmen's compensation fund the premiums provided by this chapter shall not be liable to respond in damages at common law or by statute for the injury or death of any employee however occurring.

Under the workmen's compensation act, said the court an employer is liable to employees for "personal injuries" or death sustained in the course of and resulting from employment. If the injury is due to a disease, that injury is compensable only if the disease is attributable to an exposure or injury at a definite time. In the present case, the court continued, the disease is attributable, not to exposure or injury at a definite time, but to exposure extending through a long course of employment. It constitutes an occupational disease for which no compensation is provided by the act. That being so, the question to be determined is: Does the exempting clause of the workmen's compensation act, above quoted, exempt an employer who is protected by the act from liability for an injury to an employee arising from disease contracted in the course of employment through negligence of the employer though the injury be not compensable under the act? At common law, said the court, an employer is liable in damages for the employee's traumatic injury and for disease contracted by the employee, where the injury or disease is caused by negligence of the employer. No liability attaches for occupational disease not produced by negligence. By the workmen's compensation act, compensation is provided for an employee who suffers a traumatic injury and where he suffers disease attributable to a specific and definite mishap. This burden is borne by industry as a whole and is met by the premiums paid by the employers. In return, the employers are relieved from

the burden of common law actions in such matters. The only element of common law liability which remains is predicated on disease occasioned to employees by the negligence of employers. Not only would constrained construction of the statutory exemption of liability result in precluding employees from maintaining damage actions for disease suffered on account of negligence of employers said the court, but immunity of employers from such liability would tend to foster negligence of a kind likely to produce disease. It must not be held that such right of action is taken from employees unless the statutory language is clear and concise and not subject to any other reasonable construction. It is difficult, continued the court, to perceive a satisfactory and reasonable basis for exemption of employers from liability for disease caused by their negligence, such disease being not compensable under the workmen's compensation act. Furthermore, under the workmen's compensation acts of most of the states, employers are not exempt from liability for damages in noncompensable cases. Thus to construe the exempting clause in the West Virginia act as not exempting employers from liability for damages in noncompensable cases would place such employers on the same footing as employers in the other states, and such construction would involve no special nor exceptional hardship. The phraseology of the exempting clause, continued the court, lends itself to the construction that the legislature intended not to exempt employers from liability for noncompensable disease caused by the negligence of the employer or from death resulting from such disease. This clause, the court pointed out, relieves an employer from liability for "injury or death" of an employee, provided "the injured employee" has remained in the employer's service with notice that the employer was a subscriber to the workmen's compensation fund. Note the language "injury or death" and "injured employee," said the court. The legislature in making provision in the act for injury to workmen was giving primary consideration to injuries other than disease. The phrase "injury or death" and "injured employee" as used in the exempting clause must therefore be taken to mean an employee who had been hurt, or sustained injury by reason of a trauma. It is from liability for such a traumatic injury that the clause under discussion exempts an employer. The contention of the employer, therefore, was in the opinion of the Supreme Court of Appeals untenable and the action of the trial court in overruling the employer's demurrer was affirmed.—*Jones & Rinehart and Dennis Co. (H. L. A.)* 168 S. E. 482

Privileged Communications No Inference to Be Drawn from Failure of Patient to Waive Privilege—Section 1536, Code of Mississippi, 1930, declares that all communications made to a physician by a patient are privileged and that only a patient may waive this privilege. No inference may be drawn said the Supreme Court of Mississippi, unfavorable to a patient because he fails to waive this privilege. If this were permitted, the statutory privilege accorded the patient would be nullified. In *Pennsylvania R. Co. v. Durkee* (C. C. A.) 147 F. 99 8 Ann. Cas. 790, the court said "To hold that, because the patient does not waive or abandon the prohibition inferences adverse to his side of the controversy may be drawn by the jury would be to fritter away the protection it was intended to afford. When it is the legal right of a party not to have some specific piece of testimony marshaled against him he may exercise that right without making it the subject of comment for the jury."—*Hobson & McLeod (Miss.)*, 147 So. 778

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Treatment of Respiratory Failure in Acute Poliomyelitis.—Brahm and Lennarsky state that the timely administration of sedatives and parenteral injections of fluid, laxatives or other medication in respiratory embarrassment in epidemic poliomyelitis will avoid interference with the artificial respiration. Every effort should be made to prevent a rise in the temperature of the air inside the respirator. The paralyzed skeletal muscles should receive immediate attention. In some instances, removal of the patient from the respirator is not a simple matter. The simplest method is to lower the pressure gradually and to permit the motor to run. The patient then breathes of his own accord inside the chamber. Until the apparatus the technique of treatment or both are improved the authors do not advise the treatment of patients with slight or moderate respiratory distress in the respirator. Repeated small doses of sedatives and continued reassurances will make such patients comfortable and enable them to rest. Their twelve patients with bulbar lesions apparently associated with involvement of the vital centers all died. Among the patients with only spinal lesions, twelve died in the respirator and four within six weeks after treatment. One subsequent death five months after treatment was due to pneumonia. Another death which occurred seven months after the patient's discharge, was due to pneumothorax and pneumonia. After seven months twelve of the authors' thirty-four patients with spinal lesions are alive. This does not compare favorably with the results in cases of spinal lesions reported by Wilson. He advised that the respirator be used early, long before the appearance of cyanosis before there is evidence of marked dyspnea and at the first evidence of the existence of any paralysis of the respiratory muscles. The only other series of cases reported is that by Shaw and his associates. They treated ten patients with paralysis of the diaphragm and intercostal muscles with three deaths. Five other patients with bulbar lesions all died. The authors point out that the Drinker respirator is a notable advance in the treatment of respiratory failure in poliomyelitis.

Effect of Vitamin B Diet on Tuberculous Children.—Crimm and his associates divided forty tuberculous and non-tuberculous children of approximately normal weight ranging in age from 3 to 17 years into four groups which were designated as the control mineral mixture, vitamin B and special cereal groups. The daily administration of a special cereal

mixture composed of 53 per cent of farina, 18 per cent of oatmeal, 10 per cent of cornmeal, 15 per cent of wheat germ, 2 per cent of bonemeal, 1 per cent of dried brewers' yeast and 1 per cent of alfalfa leaf meal, which supplied in liberal amounts calcium, phosphorus, iron, copper and vitamins A, B, C and G in the diet of the group fed this mixture, was accompanied by an increase in weight and in hemoglobin over the controls. The serum calcium rose to the highest concentration in the group fed the special cereal. The serum calcium and phosphorus rose to higher concentrations in the groups fed the mineral mixture, the vitamin B complex concentrate and the special cereal than in the control group. The data suggest that the vitamin B content of the special cereal was largely responsible for the increased gain in weight. The mineral content of the special cereal was apparently responsible for the increase in hemoglobin. The addition of vitamin B concentrate or of minerals to a regular diet does not seem to be as satisfactory as the feeding of a combination of the two in the form of a special cereal which contains in addition vitamins A and C.

Sensitive Test for Subclinical Scurvy in Man.—The studies of Dalldorf indicate that the capillary resistance test as estimated by Hecht's method, may be used as a criterion of subclinical scurvy. Changes in values in an individual case or differences in average values for groups are of diagnostic significance. In a group of children from poor homes the incidence of subclinical scurvy, as estimated by this method, was found to be between 35 and 66 per cent.

- Preparation of Dextrose and Saline Solutions and Apparatus for Intravenous and Subcutaneous Use. S. A. Thompson. New York.—p. 127.

Visualization of Peripheral Nerves.—Saito and his associates visualized roentgenologically the peripheral nerves in nine patients by means of injection of the emulsion of iodized poppy-seed oil into the intraneural or interneural sphere and it was ascertained that no unfavorable symptoms followed during and after the injection (pain, fever, neuralgia or paralysis). By intraneural injection the emulsion will diffuse toward the center of the part while in the case of interneural injection it will diffuse toward the periphery. In the case of intraneural injection the resorption of the injected emulsion will take much longer than in the case of interneural injection. By these methods the authors were successful not only in neurography but in epidural and extradural myelography when the emulsion was injected through the sacral hiatus. They believe that by the foregoing methods some particular diseases of the nerves such as neuritis, the amputation of nerves, neurinoma and spinal tumor, can be examined.

Coramine in Denarcotization and Resuscitation.—Wood administered 2 cc. of a 25 per cent solution of pyridine beta-carbamic acid (coramine), immediately on return to bed and

according to special indications, to eighty-two patients in whom tribrom-ethanol was used as the basal anesthetic. From his observations in these cases he concludes that 1 The 25 per cent solution of pyridine betacarboxic acid is a definite stimulant to respiration and circulation depressed by tribrom ethanol, solution of procaine (novol) or surgical shock. 2 The toxicity of the 25 per cent solution is low, and large repeated doses may be employed if the necessity exists. The author illustrates this in one of his cases, in which 28 cc was given during a period of sixteen hours with apparently excellent results. Further, in this series there was no depression after the immediate stimulation. 3 The use of the solution is suggested in all cases in which early recovery from anesthesia, especially the tribrom ethanol-ether sequence, is desired.

Spontaneous Perforation of the Bladder—Hepler and Eikenberry report two cases of spontaneous perforation by sequestrums with the formation of osteovesical fistulas and displacement of the bladder secondary to osteomyelitis of the pelvis in which attention was called to the complication by persistent pyuria, and two cases without perforation in which there were no urinary symptoms. In all four cases the marked displacement of the bladder was due to the intrapelvic intrusion of an enormous involucrum. The authors feel that the complication is fairly frequent from the fact that it was present in each of the four cases of osteomyelitis of the pelvis that they have had the opportunity to examine. The absence of signs and symptoms referable to the urinary tract accounts for the failure to consider this possible urinary complication. Even in the two cases with perforation there were no subjective symptoms, and examination was undertaken because of persistent pyuria. The clinical significance of the condition lies in the possibility of perforation of the bladder, which occurred in two cases and which might be assumed to be impending in the others in which the engendering factors were the same. This should be an additional reason for early and thorough drainage of all suppurative processes of the hip joint or the pelvic bones. The operation for osteovesical fistula is at times difficult because of the firm adhesions of the contiguous portion of the bladder to the involucrum and the infiltration about the fistula offering danger of laceration. Healing is rapid and the operative results are good. Once corrected the condition does not tend to recur provided adequate drainage of the osteomyelitis is established.

- *Comparative Study of Muller's Conglobation Reaction in Syphilis with Wassermann Reaction and Another Precipitin Test. I. Chang. Shanghai, China—p. 550

Umbilical Cord Wassermann Tests—Roby and Lembcke believe that umbilical cord Wassermann reactions reflect almost exactly the condition of the mother's blood at the time of labor. If the mother's blood is negative the cord blood will be negative.

If positive, the cord blood will be equally positive. The substance causing the Wassermann reaction passes out of the child's blood in most cases by the end of two months' time leaving the child's blood frankly negative, provided the child actually does not have syphilis. If the child actually has syphilis, the Wassermann reaction, after a number of days and weeks, will remain as strongly positive as it was in the cord blood. The decreasing Wassermann reaction means that the child does not have syphilis and that treatment should be withheld. If treatment is instituted on these new-born children with positive cord blood not too much credit should be given to the drug used. The authors are in accord with Dunham concerning the Wassermann reactions and also with Denham, White, Brahmachari and Marty that the drug (sulpharsphenamine) may be regarded as one of the most innocuous at present in use, its lack of toxicity being most marked in comparison with its high efficacy.

Agranulocytosis Following Neoarsphenamine Therapy—Stratton reports a case of granulocytopenia with ulcerations of the skin following neoarsphenamine therapy. There was a rapid recovery under injections of pentnucleotide and sodium thiosulphate by mouth. Arsenic medication (using a pentavalent instead of the trivalent compound) was resumed in thirty days without further reaction on the bone marrow. The author recommends that more frequent blood counts be made on patients undergoing antisyphilitic treatment especially those reacting in any manner to arsenic therapy.

Muller's Conglobation Reaction in Syphilis—Chang states that Muller's conglobation reaction is technically simple, is easy to read, and agrees in its results in 96 per cent of cases with the Wassermann reaction and the Kahn test. It is more sensitive than the Wassermann reaction and the Kahn test, but nonspecific reactions occasionally occur. Muller's conglobation reaction would be a good auxiliary to the Wassermann reaction. A negative Muller conglobation reaction would have more value in excluding syphilis than the Wassermann reaction or the Kahn test and a positive Muller conglobation reaction means presumably syphilis but clinical evidence must not be neglected to establish the final diagnosis.

- *Technic and Apparatus for Intrapleural Pneumolysis. J. W. Cutler. Philadelphia—p. 528

Surgical Treatment of Tuberculous Cavities—Fischel states that the peripheral cavity presents a strict indication for immediate collapse. By the early use of pneumothorax, in infiltrations that do not retrogress in a short time the formation of cavities and of adhesions may be prevented. The suspended cavity should be recognized and the distention of the cavity by adhesions and pneumothorax should be avoided. Phrenicectomy is applicable for the obliteration of cavities if and as soon as compression by pneumothorax proves unsuccessful. It can be used to great advantage in conjunction with incomplete pneumothorax or partial or total thoracoplasty. In

advanced pulmonary tuberculosis, phrenicectomy has a good hemostatic effect and is apt to improve laryngeal and intestinal tuberculosis. After partial upper thoracoplasty the closure of cavities takes place by concentric retraction. A thoracoplastic operation cannot be standardized as to its extent. No untoward effects were observed if the first stage was done on the upper ribs. Good results can be obtained by a partial upper thoracoplasty. If the cavities are collapsed first normal portions of the lung can be preserved and it may not be necessary to perform a total thoracoplasty.

Technic and Apparatus for Intrapleural Pneumolysis—Cutler describes a technic for the closed single cannula method of cutting intrapleural adhesions, based on modifications of the methods and apparatus in common use in which adhesions are accurately located by roentgenograms and fluoroscopy and the topography of the lung is outlined in mercuriochrome on the surface of the chest before the introduction of any instrument. Immediately before the operation the lung is further collapsed and the adhesions stretched by inflating with air. The pneumothorax needle is introduced at the point of entrance previously decided on for the cannula. The adhesion to be severed is selected and studied minutely by means of a diagnostic thoracoscope which brings a considerable area of the cavity of the chest into view. By means of an extension attached to the diagnostic thoracoscope a hooded lamp can be introduced to transilluminate the large blood vessels and extensions of tissue of the lung that may be included within the adhesion. Coagulation and cutting is an automatic and continuous process carried out under the direct control and vision of the thoracic surgeon by means of an operating forceps thoracoscope. By using suitable currents from a vacuum tube high frequency type of generator the adhesion is severed by diathermy. The coagulated area acts as an effective seal for the stump. Broad adhesions that are too bulky to be grasped within the elongated jaws of the thoracoscope can be severed by an operating electrotome. All the instruments employed fit interchangeably into one cannula and only one puncture of the wall of the chest is required.

Unusual Complications of Diabetes Mellitus—Vinson and Wilder report two cases of diabetes because of the discovery of unusual and so far as they know previously unrecognized complications—diffuse ulceration of the esophagus in the absence of any obstructive lesion and a similar ulceration of the trachea. The possibility of an etiologic relationship in the accompanying metabolic abnormality is considered. The first of these cases is also of interest because arteriosclerosis other than a few patches and streaks of fatty deposits in the intima that would be expected in any man of the patient's age could not be found at death. Weichselbaum and other investigators have suggested that arteriosclerosis may be the cause of diabetes in many cases

in which the two conditions are found accompanying each other, and not as is usually assumed the result of diabetes. This case adds strength to such a view. The diabetes was severe it persisted with ineffectual efforts at control for six years periods of severe acidosis occurred frequently. Under these circumstances the lipids of the blood must have been abnormally high most of the time, yet arteriosclerosis did not develop to a degree that can be considered abnormal.

Administration of Thyroxine—In six patients with myxedema whose basal metabolism varied from minus 18 per cent to minus 41 per cent during the period of myxedema, Thompson and his associates found it necessary to administer from 0.4 to 1.46 mg of the monosodium salt of thyroxine daily by mouth in order to hold the basal metabolism at the normal level. In the two patients in whom a comparison of the daily maintenance dose was made it was noted that the effect of the monosodium salt by mouth was only from one fourth to one fifth as great as that of thyroxine given intravenously in alkaline solution. Pure synthetic thyroxine had much less effect by mouth than its monosodium salt. Thyroxine for oral use had an effect greater than that of the monosodium salt and less than that of thyroxine given intravenously in alkaline solution. Thus in four patients whose basal metabolism varied from minus 31 per cent to minus 41 per cent during the period of myxedema it was necessary to administer from 0.46 to 0.73 mg daily of this product in order to hold the basal metabolism at the normal level. The effect of this substance was from two to two and a half times as great as that of the monosodium salt by mouth while in the two patients in whom the comparison was made it was only about one half as great as the effect of thyroxine given intravenously in an alkaline solution. The effects of desiccated thyroid by mouth and thyroxine intravenously or subcutaneously were the same on the basis of equivalent iodine contents. In the digestion of desiccated thyroid peptides and polypeptides of thyroxine are formed which have a wide range of solubility. The solubility of thyroxine compounds appears to be a factor in their absorption from the gastro-intestinal tract and hence in their effect on the basal metabolism.

Changes in Gastric Acidity in Peptic Ulcer—The studies of Vanzant and her associates show an increase of approximately 12 units of free acidity in the case of duodenal ulcer an increase which varied with the size of the ulcer, with the number of ulcers found at operation and with the severity of the symptoms produced. Less than 1 per cent of the patients with duodenal ulcer failed to show free acid after an Ewald test meal. In fifty cases studied the gastric acidity of patients having duodenal ulcer who after gastroenterostomy returned with jejunal ulcer was not higher than that of patients similarly operated on who after two or more years are still free from symptoms of jejunal ulcer. In 174 men having gastrojejunal ulcer the mean free acidity was lower than normal by about 4 units. The incidence of true achlorhydria was 71 per cent of normal. In the case of gastric ulcer the mean free acidity was lower than normal by about 6 units. This lowering was more marked in the cases of ulcers situated in the proximal two thirds of the stomach. The incidence of achlorhydria was half of that observed in normal persons. Practically no change from normal was found in the mean free acidity of patients having cholecystitis and cholelithiasis. No change from normal could be found in the gastric acidity of patients who had submitted to cholecystectomy. In patients who suffered from disease of the gallbladder and ulcer of the duodenum, the acidity was slightly higher than in patients presenting uncomplicated duodenal ulcer. There was no significant deviation from normal in the mean gastric acidity of patients suffering from allergic manifestations migraine psychoneurosis and chronic nervous exhaustion. Among the men presenting a psychoneurosis the incidence of achlorhydria was increased about 50 per cent and among those having migraine it was decreased about 50 per cent. In both groups the incidence of achlorhydria among women was normal. In the absence of marked organic obstruction at the pylorus it was noted that with duodenal ulcer and gastrojejunal ulcer there was a slight increase in the amount of gastric juice removed, there was also a slight increase in the presence of gastric ulcers situated in the distal two thirds of the stomach.

Pneumonia Due to Friedländer's Bacillus—Olcott reports five cases of pneumonia in which the blood at necropsy contained Friedländer's bacilli and a case in which positive cultures were obtained from the lung post mortem. The course was acute in all the cases in which death occurred in from two to ten days after the onset of acute symptoms. The patients were men between 38 and 55 years of age. Three had a definite history of alcoholism and three a history of chronic infections of the upper respiratory tract. In four the blood counts gave less than 7000 leukocytes and in one of these less than 2000 with 24 per cent large mononuclears. In four there was pneumonia of lobar distribution in one pneumonia of the lobular type, and in one lobar distribution in one lobe and lobular in another. In five a typically mucous appearance was seen on cross section. The pulmonary alveolar walls were more or less injured in all. Sections of four of the lungs showed enormous numbers of bacilli in the pulmonary alveoli while fewer bacilli were found in the other two. Large mononuclear cells in great numbers were the predominating intra-alveolar cell in these four cases with polymorphonuclears in lesser numbers. The proportions were reversed in the other two cases. The mononuclear cells are believed to be monocytes.

Sympathectomy in Fractures—Colp and his associates confirm the experimental work of others that periarterial sympathectomy has a physiologic basis for clinical application in the repair of fractures. Radiopaque visualization of the arterial tree of the lower extremity on which a femoral arterial sympathectomy was performed at Scarpa's triangle revealed an increasing vascularity in all experiments. This persisted throughout the longest period of observation (ten weeks). Callus was first detected on the sympathectomized extremities in five dogs three times on the control extremities and in one instance it was doubtful. Firm bony union was evidenced sooner on the sympathectomized side in all animals surviving a sufficient period of observation. Complete bony union as determined by obliteration of the fracture line occurred only on the sympathectomized extremity and was never noted on the control side during the period of observation.

Circular Suture of Blood Vessels—Thurston and Lamb used the original Carrel technic with the following modification. To form the posterior point of the triangle they placed two traction sutures through the edges of the vessel and closely together in the back wall. The ends of one were brought out to the right and the ends of the other to the left of the vessel. The collateral circulation is better preserved, as the artery need not be freed from its collateral vessels for so great a distance. The ends of the artery are apposed by tying the retaining stitches. An end of one of the posterior retention sutures is threaded into a number 16 straight needle and a side of the triangle is sutured. The last stitch of the line the lock stitch taken 1 mm from the traction suture prevents the line of suture from loosening or from being drawn too taut by subsequent pulling. When the second posterior traction suture is reached, the continuous suture is tied to one of its ends. The suture line is then carefully inspected, accessory sutures are taken if needed and the flow of the blood is reestablished. The distal type is removed first, and the proximal as quickly as possible. A thin strip of muscle held closely to the suture line as suggested by Bird, hastens clotting in the needle holes. When the bleeding stops the ends of the tunica adventitia are brought over the suture line by interrupted stitches the sheath of the vessel is closed and the edges of the peritoneum are apposed. From their experiments the authors conclude that surgical trauma and retardation or distortion of the blood current are the chief contributing factors to the thrombosis that occurs when blood vessels are sutured. Infection plays a minor part as a cause of blood clotting at the line of suture. Careful asepsis is essential to preclude breaking down of the line of suture. An obstructing thrombus when it occurs usually forms within a few hours after vascular repair. It is secondary usually to platelets deposited before the full flow of blood is reestablished. The increase in blood platelets does not reach its maximum until a few days after operation usually too late to influence thrombosis in the segment of repair. Solution of heparin fulfills the requirements of a satisfactory anticoagulant in suture of the blood vessels.

Transfusion of Blood in Tuberculosis—Bunsen states that small blood transfusions of from 15 to 20 cc have seemed of real value in hemoptysis. He has had four patients who stopped bleeding immediately, one shortly after transfusion and one in two weeks. Three of these have had no hemorrhage since but one had hemoptysis one year afterward. Chills and fever of varying degree were observed after the transfusion in thirty seven patients but seemed to have no deterrent effect on the subsequent progress of the cases. The author suggests that the contraindications to the use of the transfusion of blood in tuberculosis include pulmonary edema, advanced nephritis and myocarditis but in the complicating factor of nephritis which is not of long duration small transfusions of blood may be of decided value. The possibility of there being a distinctive value in the blood of a cured tuberculous patient has been considered and a record of a Pirquet reaction of donors would be of interest in this connection.

Relation of Allergy to Resistance—Clawson studied experimentally, the relation of allergy to resistance. Rabbits were made hypersensitive (allergic) to streptococci. Another series was made highly resistant to streptococci without the allergic state developing. It was found that organisms were not removed from the blood stream as rapidly in fifteen minutes in the allergic animals as in the normal animals. This suggested some harmful factor associated with the phenomenon of allergy. After two hours, however a greater number of streptococci

per gram of liver were killed in the allergic animals than in the normal animals. This difference was but slight. Organisms in the blood stream and in the liver were killed at a much greater rate in the animals that were made resistant without allergy developing than they were in either the normal or the allergic animals. The observations suggest that the allergic state is not necessary in the development of a general protective resistance to streptococci. It even seems that allergy may be harmful from the standpoint of its effect on the phagocytic cells. Probably it should not be said that allergy in general is a harmful concomitant phenomenon associated with resistance, for from the standpoint of the repair of tissues, allergy might be looked on as being useful, since the growth of connective tissue is stimulated. It seems that allergy bears no useful relation to general resistance in streptococcal infection as indicated by phagocytosis and that at times there may be a harmful relation.

Salmonella Food Poisoning—According to the experiments of Verder and Sutton, heated and filtered cultures of enteritidis strains produced no symptoms of food poisoning when fed to human volunteers or to monkeys—except in the case of one volunteer who took a culture that had been heated insufficiently to kill the contained organisms. His severe illness though entirely accidental, provides weighty evidence in favor of living bacilli, rather than thermostable toxic products being the cause of *Salmonella* food poisoning. In both man and monkeys the first sign of illness was the development of diarrhea. Cultures of the diarrheal stools were practically pure cultures of the swallowed organisms, indicating that *Salmonella* enteritidis had supplanted the normal fecal flora. The smaller the number of organisms swallowed, the longer is the period of incubation. The symptoms produced by eating cultures of *Salmonella* are not unlike those that follow the ingestion of staphylococcus toxin except that in the cases of *Salmonella* food poisoning the period of incubation is longer, the onset more gradual and the illness more prolonged. These points of difference might be explained by a gradual accumulation and gradual decrease of absorbable toxic substances in the intestine following ingestion of cultures of *Salmonella*. With a return of the normal fecal flora the prostration disappears. While in the present experiments the recently isolated strain (A 5, isolated in May, 1930, five months before the work with monkeys began) was more potent than strain 716 (isolated in 1929) the potency of strain 614 (isolated in 1928 and taken by mistake) indicates that strains maintained on artificial mediums for some time may under certain conditions be as toxic or virulent as recently isolated strains.

Progressive Bulbar Paralysis—Helfand believes that progressive bulbar paralysis is a syndrome of other disease entities, mostly of amyotrophic lateral sclerosis. A pathologic process may exist in cells without giving its clinical equivalent. The process is not confined to motor cells or definite motor tracts. It is due to a constellation of causative factors and is most likely precipitated by an exogenous toxin which influences neural as well as mesodermic tissue. Of the author's four cases three presented unmistakable amyotrophic lateral sclerosis really amyotrophic bulbar paralysis, and only one of the four presented what might be called a true progressive bulbar paralysis for this case alone was unaccompanied by a degeneration of the pyramidal tract.

*Encephalitis Complicating Measles Treatment with Convalescent Serum Intraspinal Case Report B P Storts Jr Tucson Ariz—p 330

Encephalitis Treated with Convalescent Measles Serum—Storts reports a case of encephalitis complicating measles in a boy of 7 in whom convalescent serum was used. Chloral hydrate and sodium bromide rectally and codeine hypodermically were given to control the convulsions. Coma prevailed and six hours later the rectal temperature was 107 F, the pulse 140 and the respirations 50. A hypodermoclysis of physiologic solution of sodium chloride and continuous intravenous injection of a 10 per cent solution of dextrose were given. Insulin was given with the dextrose. The next day the neck was stiff and opisthotonos was marked. The rectal temperature fluctuated from 101.4 to 108 F, the pulse rate to 130 and the respirations to 40. There were moist rales in the left side of the chest. The patient was still unconscious, but the convulsions were controlled. The spinal fluid was slightly opalescent. A second spinal puncture was done and 20 cc of fluid was withdrawn and 8 cc of recent convalescent serum was given intraspinaly. The serum was obtained from a patient two weeks convalescent from measles. The boy regained consciousness during the night of the third day of the illness, though he was still stuporous. The rectal temperature fluctuated from 100 to 103.4 F during the day. The opisthotonos was still marked. The spinal fluid cell count was 90. Again 20 cc of fluid was removed and 6 cc of convalescent serum was given intraspinaly. From here on the course was favorable. The patient was fed by gavage for three days more. The cervical rigidity and opisthotonos persisted for another ten days.

Sodium Amytal in Treatment of Eclampsia—After studying a series of forty-five cases, Lewis states that from 7½ to 15 grains (0.5 to 1 Gm) of sodium amytal given intravenously and repeated at necessary intervals will absolutely control the convulsions of eclampsia. Sodium amytal permits one to treat the patient intelligently without recurrence of the convulsions. Immediate delivery in eclampsia by radical operative procedures is unnecessary in both the mild and severe types. Rupturing the membranes seems to be the procedure of choice in inducing labor. Labor, as a rule, is allowed to terminate spontaneously. Inhalation anesthesia, other than gas oxygen should be discouraged. Cesarean section under local anesthesia is indicated in a few cases that do not respond to adequate medical treatment within six to twelve hours. Favorable or unfavorable results suggest that each case must be individualized.

Nonsurgical Treatment of Carbuncles—Ray, treating carbuncles, inserts in the center of the indurated dome a small caliber needle held in a 2 cc glass luer syringe filled with liquid phenol. The needle is carried into the central portion of the mass almost to the margin of induration turned at an angle of 45 degrees and the injection of from 2 to 5 minims (0.125 to 0.3 cc) of the fluid is made. The needle is then withdrawn but not through the skin, and three similar injections are made corresponding to the dial of the clock at 9, 12, 3 and 6. If there is considerable breaking down of the tissue this sequence cannot be followed but the areas that require treatment are injected. The injection must be made beyond the columns that are breaking down, just in the margin surrounding the inflammatory zone. The patient will experience a sharp pain at the time of injection but by the time a dressing is applied it will have subsided. The author treated 100 patients by this method without severe reactions and secured good results. The patients seen early require only one treatment and are well in from ten to fourteen days.

Treatment of Respiratory Failure in Poliomyelitis—Harper and Tennant present the results of respirator treatment in twenty-four cases of respiratory paralysis occurring during the acute stage of poliomyelitis with clinical, pathologic and bacteriologic data. The respirator was of unquestionable value in the treatment of patients whose respiratory embarrassment was due to paralysis of the intercostal muscles and diaphragm without significant bulbar involvement. It was of little or no value in the care of patients whose difficulty was bulbar in origin and may even have been harmful in some instances. In the unfavorable instances the machine overpowered the choking and coughing reflexes and in some patients even caused forcible insucking through the larynx of secretions from the throat. It hindered those other measures which were effective against aspiration, i. e., a position of hyperextension and postural drainage, suction of secretions from the pharynx, the administration of fluids by parenteral routes and nursing care. The authors' observation of ruptured alveoli and emphysema in their eight necropsies, and focal hemorrhagic pneumonema in seven of these, supports the clinical evidence that the use of the respirator is not harmless. It is not without significance that the only patients with severe bulbar injury to recover were two boys who were not put in the respirators. It is true that their respiratory difficulty was due solely to injury to the muscles of the throat and the larynx without detectable damage to the diaphragm, intercostal muscles or respiratory center. Even so they were not unlike some of the bulbar patients who succumbed, and at the height of their illness these boys were in greater respiratory distress when first put into the respirator than were some of the patients who died. The authors do not concur with the opinion of Wilson that the respirator should be used as a last resort in the pure bulbar types that have not responded to other therapy. It will be difficult to refuse the use of the respirator to these patients especially since temporary improvement is usual. Nevertheless the authors have seen no lasting improvement in such cases from this form of therapy, which, they believe, makes the ultimate prognosis poorer except in unusual instances.

Unusual Localization of Tuberculous Lesions—Halpert and Wilson report two cases in which the unusual localization of tuberculous lesions caused errors in diagnosis that were not rectified until microscopic studies were made of the tissues removed at operation. Had the possibility of such localization been borne in mind, the diagnosis of tuberculosis could probably have been made preoperatively in both cases. In one case microscopic preparations showed tuberculous ulceration with little caseation, giant cells and proliferative changes in the wall of the intestine. In a me-enteric lymph node removed simultaneously numerous typical tubercles were seen with predominating proliferative changes. There were a few areas suggestive of amyloid change. A newly prepared longitudinal section of the distal half of the appendix showed an occasional milky tubercle in the serosa. In the other case microscopic preparations showed tuberculous ulceration of the skin with typical granulation tissue and numerous giant cells. In the lymph node numerous solitary and conglomerate fibrocaseous tubercles were seen and some overgrowth of the germinal centers of the follicles.

Circumscribed Cerebral Tumors in Infants—Russell and Ellis report three cases of intracranial tumors in young infants. The cases show that progressive expansion of the skull in a young infant may in rare instances be caused by a large circumscribed tumor of the cerebrum. Such a tumor may be a glioma or a sarcoma; teratomas may also occur in a similar situation and produce similar results. The macroscopic features of such tumors suggest that early recognition of the condition followed by radical surgical treatment might be of benefit to the patient. The readiness with which the expansile skull of the infant compensates for raised intracranial pressure may result in the condition being far advanced before the patient comes under medical observation and the impossibility of making a neurologic examination in infants increases the difficulty of reaching an accurate diagnosis. In general the clinical history tends to be of short duration and deterioration is rapid after the infant first comes under observation. The tumor in one case, that of a still-born infant, was a glioma, a polar spongioblastoma.

Influence of Histamine and Pilocarpine on Gastric Secretion—Blakely and Wilkinson observed that the subcutaneous injection of pilocarpine nitrate (6 mg) was quickly followed by abundant secretion into the stomach of a clear opalescent fluid similar in appearance and usually nearly equal in volume to that produced by histamine (0.25 mg). The average ten minute volume excluding cases presenting achlorhydria was 24.8 cc with pilocarpine, as compared with 23.5 cc after histamine. The greatest ten minute volume was 84 cc in the case of histamine and 65 cc in the case of pilocarpine. In the majority of cases a maximal volume was reached within twenty minutes of the stimulus, whether by histamine or by pilocarpine after which the secretion gradually returned to its original level. A second and equal dose of histamine had an almost identical effect to the first with a tendency for a maximum to be reached a little more quickly. The response to pilocarpine was likewise fairly constant in any one case.

with an average value slightly greater after the second than after the first dose. Histamine and pilocarpine together produced a greater response than histamine alone, the average increase being about 50 per cent. In cases of pernicious anemia histamine had no effect and an almost negligible effect in the remaining cases of achlorhydria. Pilocarpine on the other hand produced a definite response in the majority of the former and in all the latter; in some cases the resultant volume was considerable.

Clinical Aspects of Branchial Fistula—Bailey points out that the statement of Wenglowksi that the branchial apparatus never leaves remnants in the neck below the level of the hyoid must be incorrect. The author presents a case which illustrates a persistent branchial cartilage—a remnant the origin of which cannot be disputed—situated in the lower third of a child's neck in the exact position in which a branchial fistula commonly opens. A cervical auricle, by its structure clearly a homologue of the pinna, is situated at the point where a branchial fistula usually opens. Histologically, a branchial fistula is usually lined by a columnar epithelium and its walls sometimes contain muscle. There is no reason why a thymic bud should contain these elements. The anatomic relationships of a branchial fistula as displayed during an operation for its extirpation are in keeping with those depicted in works on embryology as belonging to the cervical sinus and the second cleft, which persists in the goat to open into the fossa of Rosenmüller.

Pulmonary Lobectomy—Roberts and Nelson state that by their technique the mortality of lobectomy may be reduced. One of the authors' patients died from cerebral abscess ten days after operation and one from influenzal pneumonia three months after operation. Six are well and free from symptoms and two are back at work but with slight symptoms. The incision through the skin and extracostal muscles runs straight from the costal margin in front along the seventh interspace to the midline behind for lower lobe lobectomy and the fourth interspace for upper lobe lobectomy. All bleeding points are coagulated with a diathermy current. The lateral margin of the erector spinae is freed, the posterior ends of the seventh and eighth ribs are exposed, the intercostal muscles in the middle of the incision are divided for about 3 inches; the space is widened by pulling the ribs apart with small hook retractors and the parietal pleura is exposed and incised. If there is a

rush of air into the chest the opening is immediately plugged with the finger and the air allowed to enter slowly. The pleural space, the intercostal muscles and the pleura are divided rapidly for their entire length with scissors. At the posterior end this incision keeps near the lower rib so as to avoid the intercostal vessels. The erector spinae is retracted and with a pair of straight bone cutting forceps the posterior ends of the ribs above and below the incision are divided opposite the tips of the transverse processes without previous elevation of the periosteum. Before the ribs are spread apart, the adjacent pleural adhesions must be separated. The fingers of the two hands are then inserted into the chest and the ribs slowly but forcibly pulled apart for from 4 to 5 inches in an ordinary adult. An illuminated rib retractor is inserted and opened out to maintain this space. All adhesions surrounding the lower lobe must be separated and the costal surface of the upper lobe freed in order to allow it to expand. The lobes are separated along the oblique fissure. Finally the pulmonary ligament is divided as far as the inferior pulmonary vein. A pedicle will now be produced, round which the operator's finger and thumb should be able to meet. The loop of a tourniquet is slipped over the diseased lobe and kept as high up the pedicle as possible while the assistant winds in the cord and tightens it. A second tourniquet is then employed and tightened up round the lung 1½ inches distal to the first. The pleural cavity is packed off with four or five large dry gauze swabs, which also cover the margins of the wound in the wall of the chest. The pedicle is divided half-way between the cords with curved scissors. When the lobe has been removed, the pedicle is swabbed with a 1:1,000 solution of acriflavine hydrochloride and the gauze packs are removed. The pedicle is sutured with number 1 chromicized catgut on a round bodied half circle needle. This passes through the white bronchovascular area as if this were a homogeneous structure and draws it together but the fringe of lung is not included in the first two rows. The suture is continuous, starts at one end of the pedicle and after reaching the other end returns as a second row to the first point where it is tied. A third continuous suture then draws the fringe of lung tissue across the surface of the pedicle and the pedicle is buried into the under surface of the upper lobe by three or four sutures. The skin and extracostal muscles are retracted, the lateral surface of the ninth rib is exposed in the midaxillary line, and 1 inch of the rib is excised. A stab incision is made through the skin and extracostal muscles into the chest and a drainage tube is drawn from within outward. The intrathoracic portion of the tube is attached to the diaphragm by a loop of catgut so that the tip lies 1 inch below the pedicle. Pericostal sutures are inserted 1½ inches apart for the whole length of the wound.

*Progressive Lethal Granulomatous Ulceration of the Nose J P Stewart—p 657

Granulomatous Ulceration of the Nose—Stewart describes a disease to which he cannot give a definite name and whose cause is obscure. In his opinion the most descriptive term is "progressive lethal granulomatous ulceration of the nose." He reviews ten cases. The disease is practically confined to the male sex, the ratio being 9:1. Eight of the ten cases occurred between the ages of 28 and 42 years. From the clinical and microscopic appearances the author concludes that the disease is not one of tumor but essentially a pyogenic one—a chronic inflammatory process. The clinical picture is one of progressive destruction of the nose, face and pharynx. The disease is characterized by a mild leukocytosis (14,800) or a leukopenia (2,200) with the white blood cells in their normal proportions. There is prolonged and hectic fever and frequent, severe hemorrhages. The duration of the illness is from one to two years. The most marked feature is the patient's complete absence of resistance to the infection. The disease must be differentiated from ulceration occurring in the nose due to syphilis, tuberculosis, malignant disorders—agranulocytosis, mycosis and myiasis, jaws, leprosy, rhinoscleroma, leishmaniasis, rhinopharyngitis mutilans (gangosa) and trophic postencephalitic ulceration. In six of seven cases in which bacteriologic observations were made the presence of a streptococcus in combination with a staphylococcus was reported. Local applications proved unavailing. Radium treatment was employed in two cases with indefinite results but high voltage roentgen therapy promised more success and deserves further trial. Eight patients died from the direct effects of the disease—sapremic cachexia and repeated hemorrhage. One survived for four months after local cure before succumbing to generalized sarcomatous cutis and one died from atypical "miners' phthisis" four years after recovery from the local disorder.

Rocking Method of Artificial Respiration—Killick and Eve compared the tidal air induced in artificial respiration by rocking on the stretcher with that produced by Schafer's method. The comparison indicated that the rocking method is at least as effective as any of the manual methods. The rocking method has the advantage over the prone pressure method of requiring less exertion in performing the necessary movements. Therefore artificial respiration can be maintained more easily over long periods. The method can be applied by an untrained operator following simple instructions as to timing. Warmth a factor so important and so commonly neglected can be adequately applied. Investigation of the circulatory changes induced by the rocking method show that their magnitude is not such as should be of clinical importance. As to the variations in the gaseous exchange with different rates of rocking

the figures show that at rates above fifteen times per minute there is a tendency to overventilate and hence wash out carbon dioxide in amounts disproportionate to the amount of oxygen that can be absorbed. Since carbon dioxide is an important stimulus to the normal activity of the respiratory center, the onset of spontaneous breathing might be delayed if its amount in the blood should be reduced too far. Since measurements by Silvester's method of lung ventilation show that rocking the stretcher ten or more times a minute induces adequate ventilation the authors conclude that for most subjects the optimal rate of rocking the stretcher lies between ten and fifteen times per minute i.e. the normal rate of breathing. In practice Schafer's method must be tried without delay and used until the rocking stretcher with blankets and hot water bottles can be brought and employed if resuscitation is delayed or inadequate. One of the authors (Eve) described the method in the *Lancet* of Nov 5 1932. The unconscious patient is placed face downward on a pivoted rockable stretcher, which is rocked 45 degrees up and down. The weight of the abdominal viscera in the head down position pushes the diaphragm up into its expiratory phase. In the feet down position, inspiration is similarly produced.

Electrical Method in Diagnosis of Thyroid Disease

—Brazier developed a method for studying the impedance of the human body to an alternating current. He terms the electrical characteristic of the human body which is under investigation the "impedance angle." In constant current work the impedance of the body can be measured by a single factor—the resistance, but with alternating currents the body functions not only as a resistance but also as a condenser. The ratio of these two factors is a property of the dielectric under observation (in this case the body), and it is a function of this ratio which shows variations in thyroid disease and which is defined as the impedance angle. The patient sits on a chair with each arm immersed to the elbow in arm baths containing 10 liters of a 1 per cent solution of sodium chloride at a temperature of about 25°C. The results are unaffected by variation of the temperature of the baths, by slight movements on the part of the patient, by the emotional state of the patient or by the strength of the current passing through the body. No preparation of the patient by resting or fasting is necessary and only a slight degree of cooperation is required. When the arms have been immersed in the baths, an alternating current sufficiently low in intensity to be imperceptible to the patient is led through him into a simple bridge circuit. The impedance offered by the patient to the current can be balanced on the bridge by adjustment of a variable condenser and a variable resistance, and the impedance angle can be calculated from the readings. Study of the normal subject shows that the impedance angle remains almost constant from day to day in the same individual and that normal groups give only a small standard deviation about the mean for the impedance angle. The values for men and for women fall into two defined groups, the women giving higher values. In order to determine whether there is a significant departure from the normal mean in cases of thyroid disease 120 women were examined. The results indicated that in thyrotoxicosis there is a marked deviation from the normal, giving high values for the impedance angle—values which in nearly all cases are far outside the standard deviation of the normal group. A comparison of the means for the groups of primary thyrotoxicosis and secondary thyrotoxicosis with that of the normal women and with the mean of a group of patients having nontoxic goiter shows that the increase in the impedance angle in thyrotoxicosis is so great that even the means for these two groups are greater than twice the standard deviation of the normal. The author observed that the severer the disease the higher the impedance angle and in this way the impedance angle can be correlated with the basal metabolic rate. The impedance angle is not dependent on the basal metabolic rate. It has been shown that in the absence of a thyroid factor the impedance angle is independent of the basal metabolic rate but in all cases in which the basal metabolic rate is raised by thyrotoxicosis, by thyroid feeding or by the injection of thyroxine or thyroid the impedance angle also will be raised. In this way the impedance angle proves a more specific test for thyroid disturbance than does the basal metabolic rate.

Fractures of the Humerus—While operating on a patient for the reduction of a typical deformity of a fracture of the surgical neck of the humerus, Frankau observed that even after freely exposing the fragments he could not obtain reposition until the arm was pulled right across the trunk to the opposite side of the body—but with this maneuver immediate and easy reposition was obtained. In the next case that came under his care he exerted strong traction under deep anesthesia in the line of the long axis of the arm for some minutes, then crossing over to the opposite side of the body he adducted the arm across the trunk, adduction being carried out to the fullest possible extent and full traction being exerted. After a few moments there was a sharp crack, caused by the lower fragment slipping over the upper fragment. A roentgenogram taken three days later showed perfect anatomic reposition of the fragments.

New Technic in Gastrojejunostomy—Beck believes that an easier access to the posterior wall of the stomach is provided by exposing it through an incision in the great omentum by the following technic. The abdomen is opened by a high right paramedian incision and a routine examination is made. If the case requires a gastrojejunostomy, the appendix is removed. An incision is made in the gastrocolic omentum parallel with the greater curvature. This incision gives free access to the lesser sac, and through it the whole of the posterior wall of the stomach can be examined. The site best suited for the anastomosis is selected and clamped. The transverse colon is then held up by an assistant and a second opening made into the lesser sac through the transverse mesocolon. A coil from the upper part of the jejunum is drawn up through the opening in the transverse mesocolon and the most proximal part that can be apposed to the stomach without strain or tension is selected and clamped. The transverse colon is returned to the abdominal cavity and the anastomosis is made in the usual way, except that it is done in the lesser sac. The edges of the opening in the transverse mesocolon are fixed to the jejunum by a few interrupted sutures and the opening in the gastrocolic omentum is closed. The author has found this method to have many advantages over the orthodox one.

Multiple Growths in Esophageal Cancer—In a series of forty cases of esophageal cancer, McGibbon encountered four in which the patient proved to have more than one growth. One was a primary double carcinoma. Two cases illustrated the spread of esophageal carcinoma by lymphatic permeation. This method of spread is similar to that which occurs in other organs, via the submucous lymph nodes, the secondary growths are upshoots to the surface, and the intervening mucous membrane appears normal. The other case is an example of spread by implantation. It is probable that during an esophagoscopy the under surface of the tongue was injured and that carcinomatous cells were implanted either from the instruments or during postanesthetic vomiting.

Possible Role of Pancreatic Juice in Production of Certain Acute Cholecystitides E. Stulz and R. Bruer—p. 1928

Effects of Sodium Salt of Cinchophen on Cholesterin—Chiray and his associates studied the action of cinchophen on the liver. Their method consisted essentially in the collection of C bile before the intravenous injection of 5 cc of a neutral aqueous solution of a sodium salt of cinchophen and at periodic intervals after its injection and in the determination of the volume of bile and the concentration of bile pigments of each specimen collected. In persons with a healthy liver, the intravenous injection of a sodium salt of cinchophen always causes a marked stimulus to the pigmentary function of the hepatic cell. In persons with hepatic disease, following a similar injection, the pigmentary function is decreased or remains unchanged in more than half of the cases. This is undoubtedly due to a functional disturbance of the hepatic cell. The results obtained up till now are insufficient to permit evaluation of the hepatic function by means of the cinchophen test. They do not as yet give precise information as to the presence or absence of danger in a surgical intervention from the standpoint of a normal or deficient hepatic parenchyma. Increased observation and biopsies on patients in whom the cinchophen test demonstrated a hepatic deficiency may yield this information and may also explain why in some cases, in which clinically the liver appears diseased, it responds satisfactorily to cinchophen. The technic of the method may also be improved as the long duration of the drainage risks the mixture of gastric juice with the bile. Despite these reservations, the authors think that the test has at least a theoretical interest. It does not present any danger and it constitutes a selective examination of the pigmentary function of the hepatic cell which is one of the most important manifestations of the cellular activity of the liver.

- *Menstrual Fever in Tuberculous Women J. Lecloux and C. Carez—p. 609
*Virus of Exanthematic Rat Typhus in Rats from Ghent and Port of Antwerp A. Van Meirhaeghe—p. 653

Menstrual Fever in Tuberculous Women—Lecloux and Carez studied the menstrual periods of 309 women affected with pulmonary tuberculosis in all stages. They found that the menstrual period is often a critical period and that the thermic instability of these patients is often accentuated at this time, particularly if the disease is in a stage of evolution. In most of the patients in whom the disease is stabilized, the menstrual period does not differ from a thermic point of view from the intermenstrual period. The more severe the lesions and their evolution the more abnormal are the menstrual thermic variations. During the course of hygienic and dietetic treatment, the progressive return of the menstrual temperature curves to normal marks rather well the stabilization of tuberculous lesions. It is the same during treatment by efficacious collapse therapy. The improvement of the general condition alone, while certain lesions continue to evolve, does not seem to bring the disturbed temperature curves back to normal. Most of the grave incidents in tuberculous women being treated in a sanatorium occurred during the menstrual periods. It is also during the menstrual period that most of the common and serious accidents inherent in pneumothorax therapy occur.

Internal and External Secretion of Pancreas—Lucchi stimulated the external pancreatic secretion of thirteen patients by introducing into the duodenum from 60 to 70 cc of an 8

per thousand solution of hydrochloric acid. The solution was well tolerated by the majority of the patients. The glycemic curve was studied before the test and every five, ten, twenty, thirty five and sixty minutes after it. The majority of cases showed a lowering of the glycemic curve. The hypoglycemia was found never less than twenty minutes after administration of the solution and in several cases was preceded by a slight and temporary hyperglycemia. The author maintains that there is a certain degree of correlation between the secretion thus brought on and the internal pancreatic secretion. In the light of a number of factors that cannot be eliminated, it is not improbable that a disturbance of equilibrium of the vegetative nervous system is the cause of symptoms developing immediately after introduction of the liquid into the duodenum such as general malaise, flushing of the face and brief hyperglycemia.

New Species of Genus *Proteus*—Magalhães and R. Muniz Aragão —p. 815

Neurotrophic Infection—A. J. de Siqueira —p. 817

New Species of Genus *Proteus*—Magalhães and Muniz Aragão isolated an organism of the Genus *proteus* from pure cultures of the pus of an infant having otitis media. The organism was the etiologic agent of the disease. The agglutination test with the blood serum of the patient was positive with a titration of 1:600. An autovaccine prepared from the micro organism gave satisfactory results. According to Bergey's classification, the morphologic and cultural characteristics of the micro organism showed that it belonged to the group of *Proteus americanus*, discovered by Pacheco in 1928 since it produces no action on sucrose, mannitol and salicin, is motile and produces acid and gas in glycerin. Nevertheless, the new organism ferments galactose with production of gas and acid and does not have any action on glycerin as opposed to *Proteus americanus*. The author believes that the organism is a new species of the Genus *proteus* and proposes to name it *Proteus panamericanus*.

Rapid Pregnancy Reaction with Mature Mice—R. Bruhl and K. Hollstein —p. 604

Hormonic Function of Granulosa Cell Tumor—Dworzak and Podleschka call attention to the fact that hypertrophy of the uterine musculature and of the uterine mucosa as evidenced by genital hemorrhages, and hypertrophy (sometimes with secretion) of the breasts are frequent attendant phenomena

of granulosa cell tumors. Hypertrophy of the uterine mucosa, usually in the form of a glandular cystic hyperplasia but occasionally in the form of a decidua, is almost always present. These changes indicate a hormonal function of the granulosa cell tumor. However, exact analyses of the hormone production of granulosa cell tumors are still scarce. In studies on the hormone production of granulosa cell tumors, the authors found that even a fivefold concentration of the urine of the patient produced in the test animals only the reaction I of the anterior hypophysis. Since this reaction often is elicitable with urine of women presenting malignant genital tumors, and also after castration and during the menopause, it is of course not specific for the granulosa cell tumor. The production of follicular hormone, however, is of greater significance. Experiments have shown that the healthy woman eliminates during the intermenstrual period from 2 to 3 mouse units of this hormone in each liter of urine. In the woman with granulosa cell tumor observed by the authors, the follicular hormone amounted to 50 units per liter. The prolonged influence of such large quantities of hormone must eventually affect the uterus and in the case under consideration they caused considerable enlargement of the uterus and glandular cystic hyperplasia of its mucous membrane. Because a decidua develops in some cases of granulosa cell tumor, the authors assume that in these cases another hormone, that of the corpus luteum, may be produced by the tumor. They think that in many instances it will be possible to diagnose a granulosa cell tumor before the operation but that it is advisable to have a frozen section made in the course of the operation. In the event that the examination of the frozen section corroborates the diagnosis, the operation should be made as radical as possible and should then be followed by irradiations. The tests for the presence of the follicular hormone should be repeated from time to time for in this manner recurrences may be detected.

Pregnancy Reaction on Basis of General Stimulation of Cells—Popoff and Dimitrowa demonstrate that it is possible to detect the flooding of the pregnant organism with hormones by a reaction that is based on the general cellular stimulation. They employ cysts of *Euglena gracilis* because a rapid and sure reaction to stimuli is characteristic of these cysts. The authors tried the cysts first in tests on hypophyseal preparations and then on urines from pregnant women on normal urines and on urines eliminated shortly before or during menstruation. They reach the conclusion that the *Euglena* cyst reaction has a high degree of exactness, almost comparable to that of the Aschheim-Zondek reaction. As far as the rapidity is concerned, it is superior to the latter reaction, because it can be read in twenty-four hours. However, its execution and reading present great difficulties and it requires more practice than the Aschheim-Zondek reaction. An increase in the stimulating action of urines is demonstrable also a few days previous to and during menstruation, which indicates that during this time the organism is likewise flooded with hormones. This fact which had been demonstrated by other methods, was thus corroborated by the *Euglena* cyst reaction. The authors point out that the same cell stimulating substances can be demonstrated also by an acceleration of yeast fermentation. However, in spite of a reliable basis, the latter method is still subject to errors in the technic and can be used only together with the *Euglena* cyst reaction. In this connection the authors call attention to the action exerted by the urine from pregnant women on the germination of certain plant seeds, a phenomenon already pointed out by others.

Changes in Suprarenals During Pregnancy—Guthmann and Voelcker observed in studies on white mice that pregnancy produces a noticeable increase in the size of the suprarenals. The enlargement of the medulla was greater than that of the cortex. Histologic examination disclosed that pregnancy increases the blood perfusion, loosens the tissues, produces a transformation in certain layers and effects an increase in the lipid content. The pregnancy changes appear in different species of animals in different portions of the organ. In the same species individual changes occur but these involve less the type than the degree of the changes. A relation between the severity of changes and the length of the pregnancy could not be detected. The authors conclude that the measurements

as well as the histologic changes indicate an increased function of the medulla and of the cortex of the suprarenals during pregnancy

Suppurative Tenosynovitis of Hand—Deicke presents a follow-up study of 200 cases of severe infections of the tendon sheaths of the hand treated at the surgical clinic of the University of Leipzig. Of these, 129 were designated as phlegmons of the sheaths and 71 as panaritria or simple felons. The streptococcus was the causative agent in 72 per cent and the staphylococcus in 28 per cent. Involvement of the forearm took place in sixty-one cases by passage of pus from tendon sheaths and from the palmar spaces into the deep intermuscular septums of the forearm. Pus from the midpalmar space can burrow directly under the transverse ligament of the hand while pus from the radial and ulnar bursae must first perforate it. Necrosis of the sheath and suppuration of the bone or the joint resulted in stiffness of the involved finger. A far more dangerous complication is suppuration of the wrist joint which develops by extension from the radial bursa by way of the short tendon sheath of the flexor carpi radialis muscle. This complication occurred four times in the author's material and was the cause of one death, two amputations of the forearm and one completely stiff hand. In thirteen cases a severe streptococcal infection became complicated by erysipelas. Hemorrhage resulting from erosion of the radial or the ulnar artery occurred in severe long standing suppuration. Mummifying necrosis of the finger, in contrast to wet gangrene of the phlegmonous tendon sheath developed in ten cases. Fatal septicopyemia developed in ten cases in five with metastatic localization of abscesses in the bones and in five without metastatic localization. Of the concurrent constitutional diseases, diabetes played the most important part. It was present in six patients, two of whom passed into a diabetic coma and died, while in one a fatal sepsis developed. Before the introduction in 1905 of constrictive hyperemia treatment, which in the author's opinion, marks a new era in the treatment of these infections, healing with preservation of function of the fingers was exceptional. The constrictive hyperemia method permitted the use of small incisions, abandonment of packing the incision and of drains, and early recourse to movements of the fingers. The author adopted Klapp's lateral incisions on both sides of the finger missing the annular ligament. He tabulates his results as follows: mortality 8 per cent, good results in 30 per cent, fair results in 17 per cent, and bad results in 53 per cent. When felons of the sheaths alone were considered, the results were as follows: good, 46.5 per cent; fair, 23.9 per cent; and bad, 29.6 per cent. With phlegmons, good results were obtained in 20.9 per cent, fair in 13.2, and bad in 65.9 per cent. The age of the patient played an important part in the prognosis. Most of the fatalities occurred in patients past 60. The younger patients exhibited less tendency to development of complications and more frequently recovered function when complications took place. The earliest possible surgical intervention was essential. Hyperemia treatment alone was practiced in only a few cases and, as a rule, later energetic treatment became necessary in most cases.

- *Surgical Treatment of Peptic Ulcers E. Enderlen and I. Zukschwerdt—p. 849
Diagnosis, Prophylaxis and Therapy of Postoperative Disturbances of Circulation K. H. Schmidt—p. 865
Isolated Fracture of Femoral Condyle Its Operative Treatment C. Neiler—p. 871

Surgical Treatment of Peptic Ulcers—Enderlen and Zukschwerdt express the opinion that the good results obtained with gastro-enterostomy in the early history of gastric surgery

were mainly due to the fact that the operation was performed for benign pyloric stenosis in elderly people with diminished gastric secretion. The disadvantages became evident when the operation was performed in younger persons. In the authors' experience it was followed by not less than 50 per cent of peptic jejunal ulcers. They doubt that neutralization of gastric contents takes place through regurgitation from the bowel of bile and pancreatic juice. Redwitz showed in animal experiments that introduction of the entire duodenal contents into the stomach failed to neutralize its contents. The authors regard gastro-enterostomy as an operation of necessity rather than of choice and practice it in the elderly patients or when resection is not feasible. Only 28.5 per cent of the 192 gastro-enterostomies performed at the Heidelberg clinic resulted in cure. The mortality was 9.6 per cent. The incidence of peptic jejunal ulcer was 51 per cent. The younger the patient, the more likely was the development of the peptic jejunal ulcer. A single profuse hemorrhage was successfully treated by blood transfusion and withdrawal of all nourishment by mouth. Intervention was indicated for recurring hemorrhage or chronic bleeding leading to grave secondary anemia. Of the 112 cases of acute perforation treated by simple suture of the perforation 31.5 per cent remained healed. Additional gastro-enterostomy is objected to on the ground of the danger of subsequent jejunal ulcer. The authors adopted a conservative course in the treatment of the so-called threatened or walled off perforation. Of the 1100 partial gastric resections 800 were followed up. Of these 85 per cent were found to be symptom free. Recurrence of the ulcer was present in 1 per cent. Failure was due to objective causes such as ventral hernia, unequal length of anastomotic loops and gastritis in 5 per cent. While considering partial gastric resection as the best surgical procedure, they do not regard it as unfailing. Gastric secretion after resection is diminished in quantity but not in quality. They found in man and in animals that the lost chemical phase of secretion may return. The stimulus for it proceeds from the bowel. For these reasons they resect at least two thirds of the stomach. Too extensive resection on the other hand, may lead to pernicious anemia. They point out that it is quite possible to leave an ulcer behind and that narrowing of the anastomosis and ventral hernia may take place. Adhesions as the cause of postoperative complaints are discredited. That the importance of residual gastritis has been exaggerated is evident from the fact that in the majority of sixty-six cases in which after a resection, roentgenologic evidence of residual gastritis was present, there were no subjective complaints. They emphasize the importance of psychic factors and the desirability of including the internist in the treatment of postoperative cases.

Psychiatric Testimony in Penal and Civil Courts K. Schneider—p. 1739
Thyroid and Carbohydrate Metabolism Grafe—p. 1741

Intravenous Folliculin Therapy—In a large percentage of genital hemorrhages traceable to irritations of the uterine adnexa, Spiegel obtained good results with the intravenous injection of folliculin. In other cases in which folliculin proved ineffective, prolan produced a temporary improvement. The author gained the impression that prolan is effective in the absence of adnexal disturbances while folliculin produces results in the presence of disturbances of the adnexa. Further investigations will be necessary to prove this theory. He resorted to intravenous injections because quick results were required. The usual dose was 1 cc (= 100 units). If on the following day the hemorrhage had not ceased the injection was repeated with the same dose and if necessary a third dose was administered. However if this was not effective the folliculin therapy was considered a failure and prolan was tried. In discussing the mode of action the author points out that the therapeutic efficacy of such small quantities of hormones is probably the result of

a hormonal stimulus which effects an instantaneous alteration in the hormone content and that this in turn leads to the cessation of the genital hemorrhage.

Material for Racial Studies—Giving a short outline of the various phases of the growth process Zeller shows that at the end of the period of puberty the human subject comes closest to its genotype and that neither before nor after this period does he reach such a degree of genotypical representation. Consequently this time of life is best suited for the determination of the familial and racial characteristics of an individual and it is advisable that only persons of this stage of development be used as material for racial studies.

Beer and Health—Schmidt discusses the alcohol content certain aspects of the fermentation and other factors that are important in the preparation of beer. He stresses the necessity of meticulously hygienic conditions. He says that in light lager beer the alcohol content should not exceed 3 per cent by weight. He considers the consumption of larger quantities of beer with an alcohol content of over 4 per cent by weight injurious to the health. He does not entirely oppose the preparation of stronger beers but he thinks that they should be taxed highly. As a general health rule for the consumption of all alcoholic beverages he advises that one should never take a drink without being sure that the stomach contains some food.

Erroneous Granting of Disability Compensation and Possibility of Withdrawing It A. Haase—p. 1827

Epidemic of Pfeiffer's Glandular Fever—Schulz observed thirty-five cases of glandular fever from May until July. During the prodromal stage adults frequently complain of fatigue and drowsiness, while children become irritable and unmanageable. Profuse sweats, lack of appetite, headaches and abdominal pains are quite frequent. This period usually lasts a few days, but it may persist for three weeks. The blood picture, with its pathologic lymphocytes, is decisive in the diagnosis. The prognosis is favorable. After citing several other epidemics of glandular fever from the literature the author discusses the treatment. He counteracts the fever with amidopyrin. He treats the painful swellings of the lymph nodes with hot oil or paraffin poultices, and solutions of hydrogen dioxide are used for gargling. He recommends also the latter measure as a prophylactic for those who come in contact with patients who have glandular fever.

Cause of Death in Electrical Accidents—On the basis of studies on dogs and rabbits, Koepfen assumes that the central nervous system is not impaired directly by the electric current but rather by way of an irritation of the circulatory system. He also points out that since the cranium provides great resistance direct impairment of the brain seems hardly possible. Registration of the respiration and of the cardiac activity revealed that the electric current paralyzed first the cardiac system and after that the respiratory center. The electrocardiogram discloses cardiac fibrillation. Anatomical investigations show that a disturbance in the cardiac vessels predominates. The author reaches the conclusion that death from an electric current is death from impairment of the cardiac vessels. The observations are important for the treatment in that they indicate that artificial respiration alone is not sufficient and that the disturbance in the cardiac vessels requires medicinal therapy.

Diagnosis of Latent Cardiac Insufficiency—Barth points out that failure to recognize latent insufficiency of the circula-

tory apparatus is the cause of two of the most deplorable and unfortunately also most frequent mistakes in the treatment of patients with heart disease: (1) when a heart which is in need of rest is being stimulated and (2) when a heart which requires exercise is given rest. The latter is of course a rarer occurrence. As the most significant somatic symptoms that should call the physician's attention to the possibility of latent cardiac insufficiency the author mentions gastric catarrh, tympanitis, a feeling of fullness in the epigastrium, constipation, lack of appetite, soreness of the muscles of the neck, pain in the throat flat and easily tiring voice, headache, general debility, a feeling of heaviness in the legs, dizziness, particularly on arising in the morning, hemorrhoids and pain in the pelvis due to venous congestion, insomnia, particularly a too early awakening, increased sweating, nycturia and decrease in virility. The psychic changes occurring in these subjects are increased irritability, moodiness, frequent depression, impatience, restlessness, anxiety, lack of sexual desire, forgetfulness and indecision.

Fever Therapy in Acute Gonorrhea—On the basis of comparative investigations on the value of nonspecific and specific fever therapy in acute gonorrhea in men, Grüneberg and Liebmann reach the following conclusions. A noticeable result can be obtained only if local treatment is employed simultaneously. In new superficial anterior gonorrhea, the fever therapy in order to shorten the course of the disease, must produce temperatures of more than 39 C (102.2 F) and must be accompanied by local reactions. The use of a specific fever-inducing remedy seems to give no particular advantages in these cases. Fever therapy is of equal value in somewhat advanced cases that are complicated by posterior involvement, slight prostatitis or infiltration. If vaccine is used temperatures of from 37.5 to 39 C (99.5 to 102.2 F) are sufficient in these cases, because the specific action plays a part. But this seems to be the case only if there is a further stimulation of immunizing processes that have been induced spontaneously.

Experiences with Serum Withdrawn After Vaccination—Linser points out that it is of great importance in infections whether the patient himself is capable of resisting the infection that is whether the organism possesses sufficient antibodies resulting from former infections or whether it has the time and power to produce new ones. Prophylaxis by vaccination previous to exposure to an infection has given good results in the campaign against infectious diseases. On the other hand passive immunization by means of animal serums has proved effective, but in many infections this is not possible, either because of certain peculiarities of the heterogenous serums or because of insufficient formation of antibodies by the animals. For this reason the author has for many years resorted to the vaccination of healthy human subjects with the respective micro organisms in order to be able to introduce into the patient a human serum rich in antibodies. He found this procedure helpful in severe gonococcal sepsis in gonorrheal epididymitis in streptococcal sepsis and even in a case of Streptococcus viridans infection. Passive immunization from one human being to another is done by first vaccinating a healthy person with the respective organism. Then after from two to four weeks serum from this person is introduced into the patient who may be given several hundred cubic centimeters of the serum. The author gained the impression that the more severe the infection the larger should be the doses of serum. In doubtful cases in which the bacteriologic diagnosis is not yet definite passive immunization should be started on an assumptive basis. This applies particularly to streptococcal

infections, especially those of the viridans type. On the basis of many years of experience the author asserts that the procedure involves no danger for the donor or the patient and that, in conferring immunity, the vaccination is even helpful for the donor.

Xanthoprotein Reaction in Blood Serum.—Kämmer studied the xanthoprotein reaction, devised by Becher, on 120 patients suffering from various disorders. The reaction is based on the presence of aromatic atomic complexes which, by the addition of concentrated nitric acid, are changed into yellow nitroderivatives. In ten out of sixteen patients with thyrotoxicosis, the xanthoprotein values were considerably increased. There was a certain parallelism between the xanthoprotein values and the basal metabolism. It was also noted that as the patient's condition improved, the xanthoprotein values decreased. In hypothyroidism the xanthoprotein values were found to be extremely low. Of twenty-seven patients with disturbances of the liver, twelve showed an increase in the xanthoprotein values. It could be demonstrated in two of these cases that an improvement produced a decrease while an exacerbation caused an increase in the xanthoprotein values. Ten out of twenty-two patients with severe heart disease showed xanthoprotein values above normal. The highest values were detected shortly before death. But there was no parallelism between the xanthoprotein values and the severity of the cardiac disorder. In three cases ending fatally the xanthoprotein values were low. Tests on fifteen patients with gastrointestinal disturbances disclosed in only two a slight increase in the xanthoprotein values. In pulmonary disturbances (pneumonia), the xanthoprotein was increased in six out of eleven cases. The highest values were found in uremia (up to 170 per cent). In the other renal disturbances the values were comparatively low. Increased xanthoprotein values were also noted in patients with cancer in two patients with blood diseases and in one case of peritoneal tuberculosis.

Calculus Gallbladder Contained in Incarcerated Umbilical Hernia. A. Demian—p. 2722.

Syndrome Complex of Right Half of Abdomen.—Titone presents the concept of a syndrome complex of the right half of the abdomen as developed by his chief, Prof. Nikola Leotta of the University of Palermo. According to this concept ulcerative disease of the stomach and duodenum, cholecystitis and appendicitis do not exist as isolated lesions. They are always associated with each other as well as with a complex of anatomic changes of the perivisceral tissues in which inflammation of the appendix is present in 100 per cent of the cases. The constant association of a diseased appendix with peptic ulcer is based on numerous observations made in the course of surgical intervention as well as on histologic studies. This association was emphasized by Pauchet, Moynihan and Paolucci.

The interrelationship is not limited to the appendix, the gall bladder and the stomach but involves in varying degrees other organs and gives rise to certain symptom complexes or syndromes. Chronic inflammation of the appendix is believed to be the original lesion, while the various abdominal syndromes develop by the extension of the process along the peritoneal surfaces. Four distinct groups are differentiated on an anatomic basis: (1) a simple syndrome of the right half of the abdomen in which inflammation of the appendix is the predominant lesion, (2) a syndrome in which gastroduodenal ulceration is the principal lesion, (3) a syndrome with cholecystitis or cholelithiasis playing the important part and (4) a group in which a combination of ulcer disease and gallstones exists together with the other lesions mentioned. The chronic peritonitis that has its origin in the disease of the appendix spreads by way of the mesenteries, the omentum, the lymph vessels and the portal vessels. It is responsible for such entities as periduodenitis, Lane's kink and perisigmoiditis. Anatomic and functional lesions of the liver and pancreas likewise exist and furnish an explanation for heretofore obscure symptoms, such as enlargement of the liver, subicteric discoloration of the skin, hyperbilirubinemia and intolerance for fats and carbohydrates, as well as certain hyperglycemias. The diagnosis of the syndrome is made by a careful analysis of the foregoing symptoms and a complete roentgenologic study of the gastrointestinal tract and of the extrahepatic bile tracts. The author stresses the necessity of a complete exploration at operation made possible by the use of a median incision 15 cm. long, removal of the appendix and of the constricting adhesions, and a proper treatment of the associated lesions.

Treatment of Hematemesis and Melena with Food.—Meulengracht advocates abundant puree diet as another well balanced diet in easily digestible and nonirritating form for patients weakened by hematemesis and melena. Of the 119 patients treated by him by this method during the last two years 5 have died in the remaining 114 the benzidine reaction of the feces became negative after an average of 10.2 days. Of the seventy-five cases of hematemesis and melena treated by him from 1928 to 1930 with regular ulcer diet with partial manition, twelve were fatal in the remaining sixty-three the benzidine test became negative after an average of 12.4 days.

Generalized Osteitis Fibrosa (Renal Form).—In Schwensen and Eiken's patient a woman aged 36 with symptoms of nephrosclerosis together with colicuria, vague "rheumatic" attacks appeared after a year and a half. Roentgen examination disclosed a generalized osteitis fibrosa with calcium deposits in the kidneys (renal form). The greatly increased calcium content of the blood and the urine pointed to disease of the parathyroid gland. On exploratory operation an adenoma of unusual size (37 Gm.) was removed. A somewhat threatening postoperative tetany was successfully treated by intravenous injection of solution of calcium chloride. In after-examination one year later the patient was well and fully capable of working.

OBSERVATIONS ON INDIVIDUAL SENSITIVENESS TO PAIN

WITH SPECIAL REFERENCE TO ABDOMINAL
DISORDERS

EMANUEL LIBMAN, M.D.

NEW YORK

For over thirty years I have been interested in the varying symptomatology of disease of the same kind occurring in different individuals. The subject of pain naturally received most attention. In this paper I shall take up mainly individual sensitiveness to pain, substitution symptoms, and radiations of pain. Some other important subjects, such as sensitiveness of diseased blood vessels and pains due to them can only be touched on.

Besides summarizing my earlier publications,¹ I shall give a survey of recent investigations. Theoretical questions will not be discussed. Nor can the vast and remarkable general literature on pain be reviewed. Like all others, I am deeply indebted to the studies of Ross, Goldscheider, Head, Mackenzie, Hurst and many others.

Many methods of gaging sensitiveness to pain have been suggested. The simple test that I employ is carried out by first pressing the thumb against the tip of the mastoid bone and then slipping the finger forward and pushing against the styloid process. Pressure on the normal mastoid bone causes no pain and therefore serves as a control. It is important not to rub the bone, because rubbing the periosteum of any bone is apt to evoke pain. Pressure in the direction of the styloid process is painful to some individuals and not to others. The sensitive point is really not the styloid process but a branch of the auricularis magnus nerve. For the sake of brevity, however, the term styloid pressure is employed. Algesimeters do not appear to be of service in practical clinical tests.

CLASSIFICATION OF GROUPS

According to the response to the test, individuals are classed as

- 1 0 sensitive
- 2 + sensitive
- 3 +++ sensitive

The first group comprises those who give no evidence of pain, and who state that they feel none. The second

includes those who evidence little pain, and also those who show none, but who in response to questioning say that they feel a little pain or give some such answer as "I feel a little pain when you press" or "It hurts when you press" or "I feel your pressure." For practical purposes it is desirable to classify groups 1 and 2 as hyposensitives. I do not refer to those in group 1 as "insensitive" because, given sufficient provocation, pain is manifested by some of them at least. Group 3 represents those who give evidence of marked pain and those who, while they may control the expression of pain, admit that the test is definitely painful. In order to indicate that there is a sharp division between hyposensitivity and sensitivity, a ++ group is not made. There is apparently no practical advantage in making any groups of those so sensitive that they might be designated ++++ sensitive, and so on.

When the styloid test is performed it is important not to press on the lower jaw. One is especially liable to do so if the latter structure is very close to the mastoid bone. There exists a sensitive point about the middle of the ramus, and when this is pressed on in addition to the sensitive point behind it, a summation occurs, which may be misleading.

If the patient experiences pain when the control pressure is exerted on the (normal) mastoid bone it must be concluded that central (cerebral) sensitization is present. If enlarged lymph nodes should be present behind the ramus of the jaw, or any condition that is in itself sensitive, other sensitive points on or near the surface of the body are available. The point that I have chosen has several advantages. It is accessible and the test is easily carried out without the patient realizing what is being done.

It is important to note that there are individuals—fortunately small in number—who, though really hyposensitive, react to the test as though they were sensitive. In such subjects, if one reverses the test by employing the styloid before the mastoid pressure, it elicits but little or no response, whereas the mastoid pressure proves painful. In other not naturally sensitive parts of the body, they act in the same way. In other words, any second stimulus gives a reaction. Because of this observation it is wise in all cases in which the styloid pressure is found sensitive to employ it again after a short interval. In the peculiar group under consideration the reaction will now be that characteristic of hyposensitivity.

Clinical experience has revealed that individuals who are sensitive to the styloid pressure on only one side react clinically like those who are hyposensitive on both sides. I do not speak of normal sensitiveness to pain, because there are apparently certain races that are preponderantly hyposensitive. For example, it was found by Dr. Leon Saul that, of thirty full-blooded male

Read before the Section on Gastro Enterology and Proctology at the Eighty Fourth Annual Session of the American Medical Association Milwaukee June 16 1933

¹ Libman Emanuel Mayo Clinic Bull 5 No 135 1924 Tr A Am Physicians 41 305 1926 Proc Staff Meet Mayo Clinic 2 273 1927 Proc Inter State Post Grad M A North America 1926 p 61 1927 Tr A Am Physicians 44 52 1929

Pueblo Indians, only one was sensitive (and he was tested on only one side). In my office practice, between 30 and 40 per cent of the patients are hyposensitive.

TOLLRANCE, SENSITIZATION, DESENSITIZATION

It is necessary to distinguish between natural sensitiveness to pain and the way in which the patient acts in response to whatever he feels. The increased or decreased response can be termed decreased or increased tolerance or reaction. The differentiation between sensitiveness (of peripheral or central origin, or both) and tolerance is rarely difficult to the trained observer.

It is advisable to call tolerance the X factor and to say that a patient has a plus X factor or a minus X factor (at times, stoicism). There are many endogenic and exogenic causes of increased or decreased tolerance, and the expression X factor is useful as indicating that there is an unknown element until, in each instance, one discovers the particular cause of the variation in tolerance. When a person's mind is engaged, pain may not be noted. During crying, sensitiveness to pain is diminished.² A patient may not feel the pain of a given condition because he fixes the involved part (for example, with cervical spondylitis, fixes the head in a more or less rotated position). On the other hand, as already mentioned, an individual may even complain of pain when a nonsensitive point is pressed on. Sir James Paget well said "For pain expected, watched for, long thought of, will come, it will come in or from the nerve center and be as bitter as any from the nerve's end."

TYPES OF SENSITIVITY

The sensitiveness that is determined by means of the test is regarded as the natural sensitivity. Besides that, one must reckon with sensitizing and desensitizing factors. These may be due to causes inside or outside the body—endogenic and exogenic influences. All these influences may have a local or a general effect, or both. A good example in connection with sensitization would be that of a patient who, after examination by a physician, is informed that he has heart disease. Following that he may, whether he has a cardiac condition or not, develop pain in the cardiac area or general pains and other symptoms. Examples of endogenic factors are worry (the worry possibly being due to an exogenic cause), fear, anger, sorrow, fatigue, diversion of attention, joy, focal infections, such intoxicants as gout and lead, and endocrine influences (especially the menopause). Among exogenic influences are all persons or conditions that affect an individual in one way or another, trauma, meteorological changes, and the like.

The physician often applies repeated, continued or strong pressure to a part of the body in order to elicit tenderness. This I designate induced sensitization. It is important in connection with the subject of induced radiations, which I shall soon discuss. It is often difficult to decide whether an exogenic sensitizing factor acts by increasing sensitiveness centrally or in the focus of disease.

Desensitization may be purposefully brought about in a number of ways, the employment of drugs being one of them. This kind of desensitization is not infrequently valuable in performing physical examinations. It may happen, for example, that when the right iliac fossa is palpated with the idea in mind of the presence

of a lesion of the appendix, there may be difficulty, because of a marked superficial hyperalgesia. However, by the use of a local anesthetic the cutaneous tenderness may at times be removed and the examination properly carried out. In cases in which there is so much local muscular spasm and tenderness that one is in doubt whether a chest condition, such as pneumonia, or an acute abdominal disease is present, a hypodermic injection of morphine (given anywhere) may diminish the muscular spasm and tenderness sufficiently to permit of a more conclusive examination.

An interesting form of sensitization is that which takes place when an exogenic or an endogenic condition sensitizes one already present. I am referring to instances in which an endogenic condition that can cause pain does not do so unless one or more other conditions are also present (secondary and multiple sensitization). For instance, a patient may have coronary artery disease to a degree not marked to give him pain, but he may experience it if a gastric disturbance is added. Under such conditions, treatment directed toward the gastric difficulty may remove a cardiac pain. A good example is that of a man suffering from carcinoma of the liver who, on sharply raising his right arm, suddenly dropped it with such severe pain that a fracture or dislocation was suspected. On examination I found evidence of perihepatitis and sensitiveness of the right trapezius muscle. What had really transpired was that the muscle had been sensitized by the perihepatitis but not sufficiently for the patient to note pain. When, however, he strained the muscle, he suffered a cumulative effect.

An interesting instance of an exogenic factor acting in a similar way is described by Billroth.³ He relates that at a concert, "when the soprano, with incredible assurance, took a high B a quarter of a tone too high," he suffered a severe attack of pain in a tooth that had never before been painful. On the following day, his dentist found that tooth carious.

HYPSENSITIVITY

I wish to pass over now to a consideration of hyposensitivity. While it may happen that a sensitive patient may show the same clinical picture as a hyposensitive one, and vice versa, there is a great tendency for the latter to feel less or none of the pain of a given disease and to present irregular radiations of pain. He is also apt, in the case of visceral disease, to suffer more in the way of symptoms due to a disturbance of the autonomic nervous system, a number of which symptoms are brought about by reflex mechanisms.

Instead of pain, the hyposensitive patient may have what is called substitution symptoms. Substitutions are classified into two groups, the one being substitution symptoms—in the strict sense—and the other, covered symptoms. The latter might just as well be called uncovered symptoms, for the reason that the patient who is sensitive does not usually complain of them (when present) because he suffers so much from the pain.

In the first group are included all symptoms that might be considered representative of pain, such as pressure, burning, numbness, prickling, tingling and other forms of paresthesia. Such symptoms as pruritus and ticklishness need special study in this connection. That ticklishness may represent pain is sug-

² It is important to keep this in mind when examinations are being made.

³ Billroth C. A. T. Wer ist Musikalisch? Berlin: Gebrüder Paetel, 1898.

gested by the observation that pressure over a diseased organ may elicit laughter in a hyposensitive patient instead of pain

Covered symptoms are of at least three kinds

A Those that appear in hyposensitive patients when pain is not predominant

A good example of this is encountered in cases of "angina pectoris" due to coronary artery disease. It is generally thought that dyspnea is not a symptom of this condition (I am not, of course, referring here to the dyspnea unaccompanied by pain, which is dependent on myocardial breakdown). If, however, the patient is hyposensitive, dyspnea may be the predominant symptom or be complained of in addition to a moderate pain. In general, I have found that severe pain covers dyspnea and that marked dyspnea covers a moderate pain. Many of the symptoms uncovered in hyposensitive patients will be noted later when disturbances of the autonomic nervous system are taken up.

B In cases in which multiple foci of the same disease process are present, the symptoms of one may cover those of another.

In a case of multiple carcinoma of the bones, the spine was very tender to percussion in several places while the patient was sitting up in bed. When standing, the spine was no longer tender, because the patient suffered very severe pain from a metastasis in one of the tarsal bones.

C When two clinically independent conditions are present, the symptoms due to one may cover the other.

Such a state of affairs is well illustrated by the story of a patient who suffered for several months from dyspnea due to emphysema, asthma and coronary artery closure (right side—clinical diagnosis). After the dyspnea had disappeared, he complained of a burning sensation on the outer side of the right thigh (meralgia paraesthetica). It developed that he had suffered from this discomfort for a number of years but that it had disappeared with the onset of the dyspnea.

The role played by substitution symptoms in hyposensitive patients is so extensive that only a few examples can be noted here. Others will be found scattered throughout the paper.

1 Patients suffering from peptic ulcer may suffer little or no pain, speaking only of fulness, pressure, burning, coldness, nausea, "gas," depression and weakness (with some, only in relation to meals), headache, dizziness and the like. The patients who perforate or bleed with little or no previous history are usually hyposensitive. The same holds true for cases of pyloric stenosis due to ulcer.

2 The hyperalgesic cutaneous areas of Head are more significant in hyposensitive individuals.

3 Most hyposensitive patients complain little or not at all of pain while undergoing dental manipulations that are usually painful, while they fear drilling because it gives them a most uncomfortable (not painful) feeling.

4 Patients who come under observation with advanced abdominal neoplasms with a short history, or none at all, usually prove to be hyposensitive. The importance of periodic health examinations is made even more evident by the studies on hyposensitivity.

5 Some patients suffering from ureteral calculus complain only of "crowding" in the iliac region. In cases of acute pancreatitis, the same complaint may be present, referred to the epigastrium.

6 In patients suffering from such disorders as subacromial bursitis or brachial neuritis, there may be complaints of paresthesias alone. Not infrequently such patients drop things that they are holding, because of weakness in the hands.

In attempting to elicit pain during the examination of hyposensitive patients, I often find it necessary to employ strong pressure. It is always essential to ask not only "Do you feel any pain?" but also "Does it hurt you when I press?" There is a great difference in the psychology of the sensitive and of the hyposensitive patient. The former knows that you are inquiring as to whether or not the examination causes pain. Most hyposensitive patients think that one is referring to spontaneous pain.

It is important to keep in mind that substitution symptoms (mainly those which are real replacements of pain) may occur in sensitive patients. In them, however, they are indicative of a mild disturbance. As indicated earlier in the paper, one must magnify in one's mind the mild symptoms of a hyposensitive patient if one wishes to calculate their real significance. In a hyposensitive patient it may happen that a moderately severe condition is characterized by substitution symptoms, and a severe one by the usual symptoms. Thus in a case of narrowing of a coronary artery there may be found dyspnea on exertion and later pain without dyspnea. Still later dizziness (substituting for gastric symptoms) may occur with attacks of pain, and finally, when a thrombosis takes place, the usual nausea and vomiting with pain.

RADIATIONS OF PAIN

As a result of the studies of Ross, Head, Mackenzie and others, much is known concerning the location of pain in various diseases and the radiation of pain. The pains and radiations that are believed to be understood and that are expected to be found may be designated as regular or usual. There are, however, many that need further observation and explanation. They may be called unusual or, better still, irregular. Among the latter are included contralateral radiations, inverse radiations and recurrent radiations.

It is practical to make a distinction between contralateral pain and contralateral radiation. A contralateral pain is one that has its initial location on the side opposite to that of the lesion. For example, if, in a case of coronary artery disease, the pain begins on the right side, that is a contralateral pain. Contralateral pains belong in the general large group of referred pains. There is no unanimity in the literature as regards the definition or conception of referred pains. The pain felt in the parietes in cases of visceral disease is by some called referred pain. The term "reflected pain" is preferable for such a pain if it is situated in the location typical for the organ involved, the hyperalgesia being designated "reflex hyperalgesia" (Mackenzie). It leads to clarity to define referred pain as that felt in a locality removed from its cause.

A contralateral radiation is one that spreads to the side opposite to that of the lesion. At times there are present radiations from a focus to the same side and also to the other side. Only those contralateral radiations seem to be of special interest in relationship to hyposensitivity which occur in the absence of any homolateral radiation. The term "purely contralateral radiation" might well be employed to characterize them.

In cases of cholelithiasis one not rarely encounters contralateral pains and contralateral radiations. In

cases of chronic obliterating appendicitis, contralateral radiations may be felt in various directions (upward to the left, directly across, or downward to the left). Contralateral pain may also occur. There are other explanations for left-sided pain in cases of appendicitis. The appendix may (rarely) be situated on the left side, or the symptoms may be produced by a reflex spasm of the descending colon (at times demonstrable by roentgen examination) and not directly by the local lesion. Of particular interest are those cases of "angina pectoris" of various origins in which the pain is felt only on the right side, or in which it is substernal and always radiates to the right side.

By an inverse radiation I mean one that radiates toward the focus of disease and not as usual from it. This is seen under a variety of conditions. In a case of coronary artery disease the pain may begin in the hypogastrium and radiate upward, or radiate from the fingers, wrist, forearm, elbow or arm of one or both sides to the precordium. I have seen a case of basilar subarachnoid hemorrhage in which the pain began in the region of the coccyx and shot upward to the base of the skull. Similarly, in a case of dysmenorrhea the pain radiated from the neck downward.

In a case in which the pain is contralateral the radiation may be inverse. This is well illustrated by a case of coronary artery occlusion in which the pain was felt in the right side of the chest (corresponding to the precordium) and always radiated toward the position of the heart.

Of great interest, I believe, is the finding that contralateral pains, purely contralateral radiations and inverse radiations are all characteristic of the hyposensitive state. Further studies are still necessary to determine their incidence in the sensitive patient. It is important clinically to realize that one should always seek the focus of disease on the side opposite to that of the position of the pain or other local symptoms if none are discoverable on the same side—and to remember always that the focus may be in a position toward as well as that from which a pain radiates.

My studies on recurrent radiation are meager. Perhaps its occurrence is infrequent. By this term I mean a radiation that returns more or less completely to its site of initiation. A better term might be "reversing radiation" or "returning radiation." Such a radiation is very significant, as one must believe that it is dependent on a disturbance in peristalsis. In a case recently observed by me the patient had complained for many months of a pain beginning to the right of the upper part of the sternum, shooting downward in a straight line to the epigastrium and then nearly all the way back. Just as the pain began to radiate upward, a gurgle was felt. The correct diagnosis (verified by operation) of carcinoma of the stomach was made before I saw the patient, because of a routine roentgenologic examination. Before that, a cardiac disorder was suspected. A knowledge of recurrent radiation might have been very helpful. Another striking instance will be given later, when I take up the important topic of muscular relaxation in relation to abdominal diagnosis.

INDUCED SENSITIZATION

The next subject, that of induced radiation, is one that has been of the greatest value in my clinical work. An induced radiation is one produced by means of the induced sensitization of which I have already spoken. When a part of the body is pressed on in order to bring out tenderness, the mistake is usually made of merely

inquiring whether or not pain is felt. It is essential to ask also where any pain is felt, and how it (possibly) radiates. If one succeeds in reproducing the pain and the radiations from which the patient is suffering, by means of induced sensitization of a certain part of the body, it may be concluded that the seat of the trouble has been located. Unfortunately not all parts of the body are adapted to this type of investigation. (The heart is made available to a certain degree by means of exertion.) All examinations should be made in a definite fashion, with intervals between them. This is an important matter, because hyposensitive patients, in particular, are apt to be desensitized by rapidly repeated examinations.

My experience with this subject is very extensive. I shall, however, present only a few brief illustrations.

1. A case of pain in the left iliac fossa traveling upward in a straight line to the left nipple and, as a result of walking, radiating at a right angle almost as far as the right nipple. Pressure on an enlarged left ovary caused exactly the same kind of pain, thus explaining its origin.

2. A case of pain in the upper part of the right side of the chest in front during an attack of rheumatic endocarditis in a patient suffering from aortic insufficiency. It was proved to be due to arteritis of the innominate artery, because it could be brought about by touching a part of the innominate artery.⁴

3. A case of recurring pains radiating from near the midline of the abdomen obliquely toward a ventral hernia resulting from an appendectomy. The hernia was not at all tender. Pressure on a large plaque on the right side of the aorta just above the bifurcation caused a pain exactly like that of which the patient complained.

4. In cases of calculous cholecystitis in hyposensitive persons, it has been a not uncommon experience to find tenderness absent in the region of the gallbladder but present in the right trapezius muscle and in the epigastrium. For the purposes of diagnosis, such trapezius tenderness may be considered equivalent to tenderness in the region of the gallbladder. In cases in which the pain is always felt on the left side the diagnosis may be made less difficult if one succeeds in inducing (or increasing a preexisting) tenderness of the trapezius and of the epigastrium by firm and repeated pressure in the region of the gallbladder, and not obtaining the same result in the left hypochondrium.

If in the course of examining patients with the aid of induced sensitization pain is not brought about one must inquire for other sensations. It is possible at times to reproduce substitution symptoms. A woman who complained of burning in the lower part of the left thorax did not feel any pain when the spine was sharply manipulated. When, however, she was asked whether she felt anything at all, she stated that the movement of the spine caused the same burning sensation for the relief of which she had come under observation. I had a similar experience with a patient who complained only of "coldness" in the left flank. On compression of the large mass present (tuberculous pyonephrosis), the same sensation was experienced.

Not only can substitution symptoms at times be reproduced but also contralateral and inverse radiations. I have already referred to a case of gallbladder disease

⁴ In one case of rheumatic endocarditis in which part of the innominate artery was tender, marked arteritis was found at postmortem examination.

in which a contralateral pain was caused by pressure in the region of the gallbladder. A good example of the induction of an inverse radiation is the following. A woman suffered from a pain beginning in the right flank and radiating to the lower part of the right iliac fossa. Pressure on the kidney and in the right iliac fossa gave no result, but pressure on an enlarged right ovary elicited exactly the same pain.

VISCERAL DISEASE

As I have already stated, the hyposensitive patient is apt to present more in the way of symptoms referable to the autonomic nervous system, a number of which are brought about by reflex mechanisms. These reflex disturbances (which have thus far been studied only in disorders of the heart and of the abdominal organs) are of great interest and make for difficulty in diagnosis. This difficulty is, however, considerably diminished by a knowledge of hyposensitivity. Instead of pain, or together with little pain, there may be present symptoms due to spasm of the cardia, the pylorus, ileocecal junction, sigmoid flexure, and the like.

Thus there may be prominent or predominant in the clinical picture such manifestations as eructation (or aerophagia), yawning, coughing, choking, hiccups and sneezing. At another time I will detail my complete observations. A few notes must suffice here.

In a case of coronary artery thrombosis, eructation (or aerophagia) may be the most important symptom. Rarely, sneezing takes the place of the usual pain of pyloric stenosis. Renal and ureteral conditions may present the picture of a more or less marked intestinal obstruction and not be accompanied by the pains characteristic of them. In cases of chronic obliterating appendicitis, the symptoms present may be entirely ascribable to spasm of the transverse or descending colon.

I have noted cough in disorders of the stomach, gallbladder, spleen, appendix, colon and kidney (it has been described by others in connection with the uterus). What is of great interest is that, in a given case, cough may be present on less and pain without cough on more marked stimulation. For example, in a young man complaining for many months of moderate abdominal pain, belching and cough, in whom a diagnosis of chronic appendicitis was made, moderate pressure elicited cough, and marked pressure, pain without cough. The latter disappeared promptly on the removal of an appendix that was thickened and completely obliterated.

Among the symptoms referable to the autonomic nervous system, so commonly encountered in hyposensitive patients, are weakness, exhaustion, syncope, collapse, sweating, vertigo the Meniere syndrome, mental depression, general nervousness, anxiety, tremulousness, distress on breathing, insomnia and dreaming. Twice in hyposensitive women, a remarkable observation was made in connection with menstruation. Instead of pain, they presented small cutaneous hemorrhages in the area in which menstrual pain is usually located (the right lower portion of the abdomen and the upper part of the thigh).

In the past few years I have noted that all of my cases of Osler syndrome (visceral lesions of the erythema group) occurred in hyposensitive patients. It is necessary to study the hematuria and the urticaria sometimes associated with disease of the abdominal organs, with reference to sensitiveness to pain.

The subject of weakness (and collapse) has been of particular interest. It has been found that, instead of pain, a visceral disease may be characterized by local or general weakness. At times the patient suffers from some pain and some weakness, instead of the severe pain that one would expect. The patient may complain of a "weak pain." This does not mean a slight pain, but weakness and pain. In hyposensitive patients suffering from rheumatic fever, there may be no complaint of pain but of general weakness, weakness in the legs or fatigue on walking. The same holds true for cases of obliterative arterial disease in the lower extremities. Dysmenorrheic women may complain of "weakness in the back" or general tiredness. A patient who collapsed and, on reviving, complained of pain in the back was found to be suffering from spondylitis without any cardiac disorder.

A study of pugilists has afforded interesting information. A number of years ago, Dr. Leon Saul tested for me ninety-seven of the leaders in New York City. Of them, 90 per cent were found to be hyposensitive. The correct figure may well be higher, because at the time the test was not always made on both sides. Some of the +++ sensitive patients may have been hyposensitive on one side. The pugilist suffers from shock, usually not from pain.

In various acute abdominal disorders, disturbances of cardiac rhythm, such as extrasystoles, tachycardias and auricular fibrillation⁵ may occur without the marked pain characteristic of the particular disorder. This state of affairs seems to be associated with hyposensitivity. It needs much further study.⁶

I wish to draw special attention to the occurrence of vertigo and of the Meniere syndrome (with or without auditory manifestations) as a substitution symptom. It is not at all infrequent in cases of coronary artery closure, and I have also found it as a substitution symptom for pain in disease of the gallbladder and even of the appendix.

In cases of "angina pectoris" of various origins one finds a particularly fertile field for investigations of the type that I am reporting. If the cases not due to disease of the coronary arteries are considered first it is found that pain is usually the one important symptom. In hyposensitive patients various substitution symptoms are encountered, some of which have already been mentioned—burning, coldness, a sense of pressure, a sensation of constriction in the chest, a feeling of swelling of the arms or forearms. If pain is present it may be contralateral, and contralateral radiations and inverse radiations of various kinds may occur.

In cases of coronary artery thrombosis apart from the fever, pericarditis and leukocytosis there is added to the pain, gastric and perhaps intestinal symptoms (diarrhea) more marked evidences of a general disturbance of the autonomic nervous system and the typical great anxiety. In hyposensitive patients the pain may be slight or absent and be replaced by the substitution symptoms just detailed. Epigastric localization is here of more frequent occurrence. Dyspnea may become the salient complaint. Vertigo may replace

⁵ Auricular fibrillation is infrequent in the course of subacute bacterial endocarditis. One of the explanations for its occurrence is infarction of the spleen in hyposensitive patients. Under such conditions there may be dyspnea or tightness of the chest but no pain.

⁶ The relationship if any between the heart block that occasionally occurs in connection with visceral disorders and the hyposensitive state is also worthy of investigation.

⁷ Occasionally a hyposensitive patient speaks of dizzy pain in the epigastrium. This is to be interpreted as pain and gastric disturbance.

the gastric disturbance.⁸ Other symptoms may become predominant, such as sweating, weakness of the extremities, general weakness and collapse. If the patient recovers from the attack of thrombosis and in walking is compelled to stop from time to time there usually occurs at such times a mild form of whatever symptom was the principal feature of the attack. In patients on whom operations have been performed for the relief of "angina pectoris" and in whom success is obtained in the relief of the pain, clinical pictures are encountered which resemble those observed in hyposensitive patients having a cause for angina pectoris but not presenting the typical clinical picture.

On analyzing the numerous observations that I have made, I have come to the following general idea: that the great difference between the hyposensitive and the sensitive patient is that in the latter the impulses travel more directly into the central nervous system. In hyposensitive individuals, they seem to be delayed in the autonomic system or linger there. If it proves true that impulses may linger in this pathway, there is available a hypothesis that may well aid in clearing up some cases of so-called visceral neurosis. Further, if one accepts the idea that impulses may travel upward or downward before entering the central nervous system, one has a clue to the understanding of some referred pains.⁹

Space is lacking for a discussion of other relevant studies. A difficult subject, but one of considerable importance, relates to disturbances in the autonomic system itself. For example, one is occasionally confronted, in the presence of tenderness in the region of the gallbladder, associated with tenderness of other abdominal organs, with making a decision as to whether a diseased gallbladder has caused sensitiveness of the autonomic nervous system or whether a disturbance of the latter (so-called sympathetic neuralgia) has led to sensitiveness of a gallbladder that may be normal. Of great interest is the observation that a chronically diseased appendix may be influenced by a disturbance in the autonomic nervous system in such a way that pain, fever and even leukocytosis may result, in the absence of any pathologic evidence of acute inflammation.

Another subject that cannot be taken up properly is that of sensitiveness of arteries and pains due to diseases of their walls alone or associated with incomplete or complete obstruction. I might note that atherosclerotic and calcific plaques may be painful and tender and may initiate remarkable radiations, and that a closure of the lumen may give rise to radiations different from those originating in thickened parts of the wall. Of great significance, I believe, is an observation made in the case of a young woman, suffering from abdominal pain and vomiting, that pressure on calcific deposits in the wall of the abdominal aorta gave rise to pain and marked nausea and itching, whereas the uninvolved parts did not.

SENSITIVITY OF MUSCLES

The last subject to which I shall refer is the sensitiveness of muscles. Tense muscles, whether natural for the patient or due to underlying disease, interfere much in making diagnoses. In intra-abdominal dis-

orders the muscular wall is apt to be tender over a localized or a wider area. It is important to make every attempt to relax these muscles. I have found that it is often of the greatest aid to turn the patient toward the side opposite that of the suspected lesion. Occasionally, turning to the same side is of more help. When a patient is thus turned, not only can one carry out a better palpation but a previously tender muscle may no longer be tender. This loss of tenderness occurs frequently in muscles that are the seat of more or less tension.

In cases of inflammatory or obstructive disorders of the kidney, not only the muscles of the back may become tender but also those of the right side of the abdomen. In such instances it may be difficult to say whether or not a renal lesion is present alone or together with an acute appendicitis. Turning the patient to the left is not infrequently of the greatest assistance, because the muscles in front may be made to relax and no longer be tender.

The short recital of one case will suffice, I believe, to make evident the great value of this muscular relaxation.

A man aged 64 took sick with abdominal pain, fever and vomiting. A leukocytosis was present. Some hours later he collapsed. A diagnosis of coronary artery thrombosis was made. When I was consulted on the following day, he was in fairly good condition, with fever and increased pulse rate. On careful inquiry the patient described his pain as starting on the right side, at about the level of the umbilicus radiating in a straight line to the left and then returning to about its original site. This radiation was considered to indicate a disturbance of peristalsis. The only tenderness present was in the lower rectus muscles. On turning the patient to the left, I observed that this muscular tenderness disappeared, and deep palpation revealed no abnormality. The tenseness of the lower rectus muscles pointed to a disorder in the lower part of the abdomen, and the reversing radiation to the intestinal tract. As no lesion could be located in the abdomen proper, it was concluded that it would be found by rectal examination (which would in any event have been carried out as a matter of routine). Without difficulty a tender exudate was palpable high up on the right side. Operative intervention disclosed a perforated gangrenous appendix.

This purposeful muscular relaxation has been of great value in connection with the consideration of the Mackenzie theory of hyperalgesia. As is well known Mackenzie believed that in visceral disease the seat of the pain is not in the viscus but is due to the reflected peripheral hyperalgesia. A number of observations has made others and myself doubtful of the general validity of the theory. In fact, evidence to the contrary can be obtained in a number of ways. One of the most available is by means of observations on tender gallbladders in hyposensitive individuals.

It is not an infrequent experience that, in a patient suffering from symptoms due to gallbladder disease there may be only moderate or no tenderness while the patient is lying on his back but marked tenderness and a widespread radiation of the pain when he is turned to the left. If the trapezius muscles were not tender before this examination, and one or both become tender (usually only the right) the inference can be made that the sensitization has been brought about by a reflex from the gallbladder. It is important in making such studies to perform a control test by pushing against the liver to either side of the gallbladder.

It is clear that if there is but little or no tenderness with the patient in the dorsal position and marked ten-

⁸ I have published notes concerning this subject in the papers cited at the beginning of my presentation.
⁹ One must of course consider the possibility of impulses spreading upward or downward in the spinal cord itself (as suggested by Behan and others) before being reflected to the periphery.

derness in the lateral position, the tenderness cannot be ascribed to the tissues of the abdominal wall. They should be as tender in one position as in the other if the seat of the pain were in them and should, in such an event, be more tender with the patient on the back, the muscular wall being then more tense. The sensitization of the trapezius muscles cannot be due to hyperalgesia of the abdominal wall.

According to my investigations, I should say that Mackenzie taught that much of what was considered to be visceral tenderness is ascribable to superficial hyperalgesia. In the sensitive patient this hyperalgesia interferes with making correct observations concerning an involved viscus itself. In the hyposensitive patient, however, the abdominal wall may be rigid and not tender, and if one succeeds in relaxing it evidence of a visceral sensitiveness may be obtained. Future studies may well reveal the diseased viscus itself is usually sensitive but that this sensitiveness is not always appreciable because of the overlying hyperalgesic abdominal wall.

COMMENT

These studies are largely preliminary in nature. It is only too evident that it will require the efforts of many observers, and over a long period, to cover the extensive field involved. Nobody realizes more than myself the liability to errors in observation and interpretation.

It is necessary to study the relationship of race, sex and age to sensitiveness to pain and to investigate fully the subjects of sensitization and desensitization. This includes the influence of pain itself, drugs and disease (especially of the nervous system).

In the future, all investigations concerning pain must take into consideration the question of natural sensitivity. Much earlier work needs repetition. In all such studies it is advisable that comparisons be made only of zero sensitive individuals (according to the classification already given) with +++ sensitives. Attempts to make finer distinctions in the course of basic investigations are liable to lead to confusion and errors.

Studies on animals may prove of value. In all the work hitherto performed it has been taken for granted that sensitiveness is the same in all animals of a given species.

The possible relationships of sensitiveness to pain to the general physical and mental character of the individual constitute another field for investigation. A comparison of sensitiveness to pain with that of the special senses should be made. A study of the relative importance to the brain of all symptoms may yield valuable results. Of significance is the fact that observations of the kind presented in this communication can be carried out without special facilities. There is therefore afforded a fruitful opportunity for studies by the practitioner.

At present the description of the clinical features of various diseases in all branches of medicine applies to individuals who are sensitive to pain. It is essential that as soon as possible there be recorded the clinical pictures of disease as occurring in the hyposensitive (and hypersensitive?). It is in these that one has the greatest difficulty in connection with diagnosis. Studies such as those here undertaken are dependent largely on what has been learned from the work of physiologists and pharmacologists and, in turn, present to them new problems to be elucidated.

CLINICAL ASPECTS OF ABDOMINAL PAIN

I. M. POTTENGER, M.D.

MONROVIA, CALIF.

Pain is a necessary part of the animal's mechanism of defense. Exaggeration of a sensory stimulus, whether it is transmitted centrally over cranial or spinal afferent nerves from the skeletal structures or over the afferent systems that accompany the sympathetics and parasympathetics to the internal viscera, may lead to discomfort or pain. Pain is the automatic danger signal that tells the individual to beware, for the normal mechanism is irritated in an abnormal manner, or even its integrity may be threatened.

In considering pain, it is necessary for the clinician to remember that the perception of painful stimuli is bound up with the patient's physiologic stability and that the complaint of sensory changes will differ greatly in different individuals. What may be a painful stimulus to one person may not be to another.

THE VISCERAL NERVOUS SYSTEM

The sympathetic or thoracolumbar and the parasympathetic or craniosacral components that make up the vegetative or autonomic nervous system form a correlating mechanism which in conditions of health brings the action of all the viscera into harmony and, further, in conjunction with the voluntary nervous system, brings visceral and skeletal activity into harmony. In conditions of disease, these nerves furnish the mechanism for creating disharmony.

Every secreting gland and every bit of smooth muscle is supplied by neurons belonging to one or both of these systems. Each of these systems consists of efferent neurons, which transmit stimuli to and produce action in structures, and afferent neurons, which pick up stimuli that originate in the various structures and carry them centrally, where they transmit them to efferent neurons and thereby translate them into action in the same organ or in other organs or parts. If the stimuli are of normal strength they are spent without disturbing physiologic function, but if of extraordinary strength they produce abnormal effects which result in either increased glandular secretion or increased muscular activity and not infrequently altered sensibility, which may be discussed for clinical convenience as a sensory reflex.

NATURE OF VISCERAL PAIN

There has been a great deal of discussion concerning the nature of visceral pain, largely because of a lack of knowledge of the visceral nervous system.

Early in the investigation of visceral pain, Lennander and Mackenzie showed that the viscera do not respond to the same character of stimuli that cause pain in somatic structures. They showed that the viscera may be cut, pinched and burned without causing pain. This necessitated that some theory be advanced to explain this difference.

Not only were clinicians surprised to learn that viscera do not contain nerves that have the property of showing the same acute pain when injured as do skeletal structures, but they have been slow to accept it, because they have been familiar with many forms of acute visceral pain in their clinical practice.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 16 1933

Visceral pain, as studied in the parietal pleura and parietal peritoneum, has been long known to be acute in character and further to be expressed immediately over the areas of inflammation. Certain inflammations of abdominal viscera, too, have been known to show acute pain on deep pressure over the organ.

These facts seemed to justify clinicians, in the absence of accurate knowledge of visceral neurology, in assuming that the viscera and skeletal structures show pain in the same manner, both at the point of injury. This opinion prevailed, regardless of the fact that it was well known that the heart refers its pain regularly to the left arm and upper portion of the chest wall and that the diaphragm refers its pain to the shoulder. Later, I pointed out that the lung expresses what discomfort there is accompanying inflammation of its tissues in the somatic areas supplied by spinal nerves that arise from the midcervical segments of the cord producing changes in sensibility in areas sometimes over the area of inflammation and sometimes removed from it, and even removed from the lung itself, as in the neck over the sternocleidomastoid and trapezius muscles.

Thus it has become evident that there is a type of visceral pain which is expressed wholly neither in nor over the pathologic process nor even in the diseased viscus itself, but at a distance, in definite areas on the surface of the body, to which it is referred. Study showed that these areas are supplied by neurons which are closely associated in the central nervous systems with the neurons which supply the viscus in question and that there is great regularity in the localization. This type of pain was therefore designated as referred pain, being referred from the visceral neuron to the skeletal neuron for its expression. It was later proved that this referred pain is segmental in nature and that it follows certain definite laws as to its localization.

Pulmonary pain is not of an acute character. Neither is pain arising in the liver, the cortex of the kidney or the spleen. In fact, the usual pain in any solid viscus so long as the inflammation is confined to the parenchyma of the organ, is not acute. A large area of a lung may be involved in a destructive process, and unless the overlying pleura takes part in the inflammation, the patient may be wholly unaware of its presence, as far as sensation is concerned. So may destruction occur in the cortex of the kidney and the parenchyma of the liver without causing a disturbance in sensibility commensurate with the destruction. This is an important fact in the argument that has been advanced to explain the nature of visceral pain. There is some factor connected with hollow viscera, on the other hand, which causes them to respond with a greater degree of sensitiveness than the solid organs, when injured. The facts of contractibility and distensibility have been considered to be the most probable cause of this difference. The intestine, the ureter or the common bile duct, which under usual conditions of physiologic activity give their possessors no evidence of their existence, under spasm or distention may cause acute pain. This fact may be interpreted as indicating that referred visceral pain, as compared with referred visceral discomfort, depends first on the character of the organ in which the stimulus arises and secondly on the severity of the stimulus. This is modified always by the particular sensitivity of the patient.

Head interpreted his classic studies on pain as indicating that the afferent nerves of the viscera are the

same as those which furnish skeletal tissues with deep and protopathic sensibility and, further, as showing that visceral pain is produced by a mechanism similar in nature to that which causes the less acute sensations found in the skeletal structures. This view is accepted by many but is rejected by others.

The visceral sensory system, like the sensory system of the deep skeletal structures, is not able to express discriminating sensibility. Under ordinary circumstances it is assumed that the afferent visceral neurons are subject to an inhibition from higher centers, which prevents the impulses from reaching the perceptive centers in the brain and, instead, are held to lower levels in the central nervous system, where they are regularly transformed into reflex effects without the individual's knowledge. Under circumstances of unusual stimulation, however, the inhibition may be overcome and the impulse transmitted to the thalamus and cortex. In case it should reach the higher centers the pain is not ascribed wholly to the viscus in which the impulses arise but is referred partly to the surface of the body. That deep pressure over inflamed visceral tissues can also produce pain which is felt in the viscus is accepted as a fact by many.

Head recognizing the segmental nature of referred pain suggested in explanation of it what has come to be known as Head's law.

When a painful stimulus is applied to a part of low sensibility in close central connection with a part of much greater sensibility, the pain produced is felt in the part of higher sensibility rather than in the part of lower sensibility to which the stimulus was actually applied.

In other words, visceral stimuli are transmitted centrally over neurons that belong to the deep or the protopathic systems—neurons of the same order as those found in the deeper skeletal tissues. Should the patient's threshold for stimuli be below normal, or should these stimuli become abnormally severe, as under conditions of undue irritation or disease, they may produce pain.

SEGMENTAL NATURE OF VISCERAL PAIN

An important factor in visceral pain is its regular localization in definite somatic areas.

It is a physiologic axiom that each part adapts itself to its particular environment and develops whatever conditions are adequate for normal physiologic action in that environment. Since the more acute types of sensibility (pain) carry with them the more ready protective reaction, and since quick protective response is not regularly needed by the internal viscera, visceral pain is not developed to the same degree of acuteness as that in the skeletal structures. Under unusual circumstances, however, such as those which produce excessive irritation or injury, the structures are not left without defense, for a pain mechanism sufficient for the emergency is called into play.

When painful visceral stimuli reach the perceptive centers in the brain the effect is regularly redistributed segmentally with the same degree of definiteness of localization as the visceral, motor and trophic reflexes that are mediated in the cord, if the effect is expressed in adjacent segments, this too follows the law that governs the spread of reflexes.

Thus visceral pain may be either narrowly localized or widely spread but always follows definite physiologic laws. In the former case it may be confined to those

segments which receive the major portion of the afferent impulses from the viscus, in the latter, it may be distributed through intersegmental neurons to either higher or lower cord levels. While each viscus receives its sympathetic nerve supply from several segments of the cord, there are usually two or three segments that may be looked on as being the chief centers of supply. The latter proves to be the principal center for the mediation of reflexes. Thus the heart receives its sympathetic supply from the upper five, six or seven thoracic segments, yet cardiac pain is most commonly expressed over neurons from the first, second and third segments.

DIFFICULTY OF COMPREHENDING REFLEX EFFECTS

Among the difficulties that are encountered in attempts to study visceral pain clinically are (1) the individual variation in reaction of different persons to stimuli of the same degree of strength, (2) the patient's inability to describe his sensations accurately, and (3) the physician's inability to comprehend and interpret properly the patient's descriptions.

The same difficulty is encountered in interpreting reflex secretory and motor effects in organs because except in cases of a low degree of physiologic stability, only major disturbances are noted and complained of by the patient. Increased tension in the skeletal muscles, which is commonly present when viscera are inflamed, too, is often neither perceived by the patient nor recognized by the examiner.

Reflex effects may be slight or severe and of short or long duration according to the reacting powers of the patient and the character of the visceral lesion that causes them. When visceral inflammation is of long duration, degeneration takes place in those skeletal tissues which take part in the reflex and may be detected either on inspection or palpation or both. It does not seem illogical to assume that degeneration may also result in those visceral tissues which are affected reflexly by chronic inflammation. Clinical experience would indicate this for it often shows a permanent functional disturbance in those viscera which are in close reflex relationship with organs that are chronically inflamed, for example the stomach in case of disease of the gallbladder. I have found this also to be the case in chronic inflammation of the lungs, pleura, peritoneum, kidney and intestine. In the case of the lungs, I have been able to establish beyond question that reflex trophic changes may be produced not only through the sympathetic afferents and spinal nerves but also through vagus afferents and the mediating cranial nerves, particularly those supplying the facial muscles, the tongue and the mucous membranes of the nose, pharynx and larynx. Paths similar to those from the lung are open for other viscera, and chronic inflammation in them is probably followed by the same effects.

DIFFERENCE IN ACUTE AND CHRONIC PAIN

Chronicity and previous disease in the viscera are often followed by altered visceral sensibility. Visceral pain may be caused by active inflammation at any time and may recur after all evidence of active inflammation in the viscus has long disappeared. This is particularly to be expected in patients of the hypersensitive class, although it is frequently met in the hyposensitive too. This chronic pain is explicable on the basis of a permanent lowering of the threshold for stimuli or even a

permanent injury to the sensory neurons, which causes them to show pain on a minimal stimulation, even though the stimulus is such that it would not be noticed were the neuron normal. This recurrent pain is not sufficiently appreciated by clinicians and is often misinterpreted as meaning active disease, when in reality it is an expression of permanent injury to the sensory neurons which causes them to respond unphysiologically.

The recurrent pain that comes on without recurrent visceral inflammation is rather a discomfort than a pain. It may appear at any time after a given viscus has been diseased.

Recurrent pain may occur in the neurons associated with any viscus that has been the seat of prolonged inflammation and possibly prolonged irritation without inflammation. It has the same segmental characteristic as the more acute pain and is sometimes difficult to differentiate from it. I have found it in those who have previously suffered from disease of the lungs, pleura, gallbladder, ulcer of the stomach and duodenum, tuberculous peritonitis, tuberculosis of the intestine, diverticulitis (personal experience), tuberculosis of the kidney and disease of the uterus and adnexa. It is also fairly well recognized in arthritis.

It seems that there is an inability on the part of these injured neurons to adapt themselves to unusual requirements of physiologic adjustment whether originating in the external or in the internal environment. The change in sensibility is manifest under many conditions, such as changes in the weather, seasonal changes, tiring, such depressive emotions as worry, discontent and unhappiness, and during menstruation. While these factors differ widely in their nature it is evident that each one calls for an unusual physiologic adjustment on the part of the patient, it will be further noticed that the individual fails to react normally only in those particular neurons which are segmentally connected with organs that were formerly diseased. Thus the patient who has had or who at the time is suffering from chronic lung trouble experiences discomfort in the segments innervated particularly by the third, fourth and fifth cervical nerves, the man who formerly had ulcer of the stomach may note pain in the skeletal areas supplied by the sixth and seventh thoracic segments to the left of the median line, while the woman with past or chronic pelvic inflammation feels the pain in the lower lumbar and sacral regions. It is a further fact that the degree of discomfort varies greatly according to the physiologic stability of the patient being most severe in the most unstable. This type of pain is inadequately appreciated. It causes both physicians and patients much needless anxiety and results in operations when no serious danger exists.

USUAL LOCATION OF PAIN FOR THE PRINCIPAL ABDOMINAL VISCERA

Since the cell bodies of the afferent neurons that supply a given viscus are located in the same segments of the cord as the efferent neurons going to the viscus, and since the cell bodies of the somatic, motor and sensory nerves, which express reflex action and referred visceral pain, are located in the same segments by knowing the connector nerve supply of an organ one also may know the skeletal nerves through which and the tissues in which, reflexes from that organ will be most apt to be expressed. In case reflex effects and referred pain spread, they are most apt to be expressed by neurons arising either above or below in segments adjacent to those which the afferent impulse enters.

In figure 1 is shown the connector neurons which bring into connection with the cord those sympathetic cells which lie in peripheral ganglions and give origin to the nerve fibers that supply each of the more important viscera. In figure 2 is shown the arrangement of the somatic segments from which one may see the location of the pain from the viscus, with corresponding segmental innervation. It will be noted that in their sympathetic nerve supply the organs may be arranged in groups and that there is some overlapping in the distribution of the neurons to the groups themselves and also in the various organs of the groups, but, regardless of this fact, the main supply to the various organs may be arranged in a definite progressive order from the upper segments to the lower, and the somatic segments showing referred pain follow a similar progressive order. This schema can be only approximately correct with present knowledge, because the exact innervation of some of the organs is still undetermined, for example, innervation of the heart is usually given as arising in the upper five or six thoracic segments, yet operations for angina have shown that even the seventh thoracic connector neuron carries painful impulses.

The first to the sixth dorsal segment give origin to connector neurons to the heart and lungs. The lungs, however, following their developmental relationships, express their somatic reflexes through cervical spinal neurons, particularly the third, fourth and fifth, while the heart joins with the corresponding thoracic nerves, showing reflex effects most commonly through the first,

Fig. 1—The connector neurons for the important thoracic, abdominal and pelvic viscera. The connecting neurons are those which belong to the thoracicolumbar outflow except those going to the diaphragm and pleura which are spinal nerves. The motor cells for the viscera are found in the various collateral ganglions. This shows that the innervation of the various viscera may be divided into groups. The heart and lungs are innervated from practically the same segments the upper first to the sixth thoracic. The stomach, liver and pancreas from the same segments fifth to the ninth thoracic. The colon, kidney and pelvic viscera from practically the same segments ninth and tenth thoracic to the third and fourth lumbar. In spite of this grouping in innervation each organ is brought in reflex connection with efferent neurons both sensory and motor, which are more or less definite in such a way that the motor and sensory reflexes do not overlap as much as might be indicated.

second and third thoracics. The major portion of the aorta, too, is supplied from the upper five or six thoracic segments and reflects through the same neurons as the heart.

Following the lungs, heart and aorta caudad in the cord, the stomach, liver, gallbladder, pancreas and small intestine are innervated from the fifth to the ninth thoracic segment, but the skeletal area in which individual organs regularly express reflexes and referred pain is more or less distinct for each organ. The stomach expresses its pain most readily in the epigas-

Fig. 2—Metamereric distribution or transverse segmentation of cutaneous areas of sensibility of the human body drawn with the limbs in the position of their embryonic growth. The series of dermatomes which successively correspond to the cervical, lumbar and sacral routes is indicated by different degrees of shading and the different segments are numbered according to the spinal nerve supplying them. The location of the principal sensory disturbances from internal viscera can be determined from this diagram. (Constructed by Luciani from Bolk's data.)

trium in the median line and on the left side in areas supplied by the sixth and seventh thoracic spinal nerves, the liver and gallbladder in the median line, and on the right side. Posteriorly, the pain may be expressed in the interscapular region through the fifth to the ninth dorsal spinal nerve, on the left side from the stomach and on the right from the liver and gallbladder. The small intestine refers its pain most readily to the median line in areas supplied by spinal sensory nerves from the eighth, ninth and tenth thoracic segments.

The colon, kidney, ureter and bladder follow next in order, being supplied by neurons arising in spinal segments from the ninth thoracic to the third lumbar. Pain from the colon is expressed most commonly through the eleventh and twelfth thoracic nerves over the lower part of the abdomen, although pain may also be expressed in the first, second and third sacral segments. Kidney pain is reflected through the tenth, eleventh and twelfth dorsal nerves and the first lumbar nerve, both anteriorly over the abdomen and thigh and posteriorly in the lumbar regions. Ureteral pain is expressed both posteriorly and anteriorly.

Bladder pain is usually expressed through the eleventh and twelfth thoracic and from the first to the third lumbar segments, although it too may refer its pain through sacral nerves. This brings it low down in the abdomen anteriorly, as expressed through thoracic nerves, and in the peritoneum and down over the leg through the sacral nerves.

It must also be remembered that all the viscera with vagal supply may transfer stimuli to the fifth cranial nerve and express pain in some of its peripheral branches.

Pottenger Sanatorium

PAIN AND TENDERNESS OF THE
ABDOMINAL WALLJOHN BERTON CARNETT, M.D.
PHILADELPHIA

Pain and tenderness occur far more frequently in the abdominal wall than in the abdominal viscera. Palpation over relaxed abdominal muscles fails completely to differentiate parietal from visceral tenderness.

Parietal tenderness and, inferentially, pain are demonstrated best by making firm palpation while the patient balloons out the abdomen and holds the abdominal muscles as tense as possible.¹ Any tenderness thereby disclosed is necessarily parietal in location, because the tense muscles prevent the examiner's fingers coming in contact with the viscera. This is a simple bedside test, requiring no special instruments, it can be carried out in less than two minutes and will give invaluable diagnostic information if it is employed, as it should be, on every patient having abdominal pain or tenderness.

Hypersensitiveness, either on pricking or stroking the abdominal skin with a pin, or on pinching a liberal fold of skin and fat, indicates parietal tenderness, but both of these tests may be negative in about 5 per cent of patients with parietal tenderness in whom the muscles are hypersensitive, as shown by palpation over the tensed muscles.

The methods of applying the tests by various diagnosticians give widely different results. Some insist on gentleness in applying pinch tests, or on simply lifting a fold of skin (without pinching) and drawing it gently away from the muscles, and fail to recognize the milder grades of tenderness. I find in normal persons that my maximum pinching effort does not cause pain and I do not hesitate to employ it before concluding that tenderness is absent in those cases in which distress is not caused by a milder pinch. Livingston² employs a vigorous pinch and twist. I prefer a pinch without a twist, as it involves only one force in estimating the comparative degree of tenderness in various areas. For routine clinical purposes, a pinch is preferable to the pin for promptly disclosing the areas of tenderness, particularly in a widespread search. The pin, however, is better than the pinch in determining the exact outlines of an area of tenderness. In a trifling percentage of cases the pin may indicate hypesthesia when pinching will disclose hyperesthesia.

Pain and tenderness of the abdominal parietes are variously interpreted by different diagnosticians. The majority fail to consider the possibility of these two symptoms being located in the abdominal wall neglect

Fig. 1—One abdominal and two thigh areas of distribution of the iliohypogastric and ilioinguinal branches of the first lumbar nerve.

to apply the special tests to determine their parietal location, and wrongly ascribe them to an existent or nonexistent lesion of an underlying viscus.

Many times when the pain and tenderness are not recognized as parietal they are attributed to malingering, hysteria or some other vague neurosis, because they are atypical of organic visceral disease or the latter has been excluded by extensive clinical and laboratory studies, often including one or more futile laparotomies.

The four areas (figs 1 and 2) of distribution of the first lumbar nerve afford many points of interest in the study of parietal pain and tenderness. The abdominal triangular area is bounded by a line from the anterior superior iliac spine running obliquely downward to the midline, which

Fig. 2—Buttock area of distribution of the first lumbar nerve.

it follows to the symphysis and returns along or a trifle above the crease of the groin to the iliac spine. This area is sharply delineated at the midline in unilateral cases. Its upper limit is distinct only in the comparatively rare clinical cases in which there is no associated involvement of the subcostal nerve. Its lower limits merge with the rectangular area about an inch wide in the upper anterior thigh overlying the flexors of the hip joint and in the female includes the upper part of the external labium. Its lower limit is commonly sharply circumscribed, as the immediately subjacent nerves are frequently not involved. From the mesial end of the preceding area a line extends downward and backward for a distance of 3 or 4 inches, thence upward and backward to the perineum, and forward to the starting point. The limits of this triangular area in the upper inner thigh often are not obscured by involvement of adjacent nerves. An irregular inverted U-shaped area in the buttock (fig 2) extends from the superior crest of the ilium downward to a transverse line at the level of the top of the great trochanter. Its posterior border follows the outline of the ilium and its anterior border is somewhat variable but lies posterior to the great trochanter. The outlines of this area are usually very distinct, as adjacent nerves commonly exhibit slight or no involvement. The first lumbar probably is involved more often than any other nerve in parietal pain and tenderness. Often spontaneous pain is felt only in one area, but even then all four areas exhibit tenderness of a similar type, i. e., pinching or pin pricking may reveal tenderness in all or none. In the latter event palpation will reveal tenderness of muscles in all. Consistent tenderness within the anatomic boundaries of the four areas serves to remove the stigma of malingering from many an honest patient.

Libman's³ classification of patients into sensitive and hyposensitive in accordance with his studies at the mastoid tip and styloid process is not applicable to cases of pain and tenderness of the abdominal parietes. His local results probably depend on the sensitivity of the overlying skin and are not a trustworthy index to other regions, as Libman himself recognizes when he

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 16, 1933.

³ Libman, Emanuel. Studies in Pain. *Tr. A. Am. Physicians* 44: 52, 1929.

finds the mastoid region on one side sensitive and on the opposite side hyposensitive. Each region of the body must be judged on its own merits for sensitivity by pinching or pin pricking and over the abdomen by palpation during voluntary tensing of the muscles.

To Libman's classification might be added a third group consisting of the hypersensitive patients who exhibit almost universal tenderness. They are usually obese and care-free, without psychopathic tendencies. By some they are regarded as individuals with a low threshold for pain. It is possible that an allergic or endocrine disturbance is responsible for their hypersensitivity. A superadded local cause—even though it is slight—is necessary in them to produce local spontaneous pain and increased local tenderness either of the abdominal wall or elsewhere.

The superficial location of parietal pain and tenderness is recognized by only a minor percentage of diagnosticians. Some of them ascribe the symptoms to parietal fibrositis or panniculitis independent of visceral lesions. The sensitive nodules of the type described in fibrositis I have encountered once on the chest, three or four times at the back of the neck in patients with neuralgic scalp aches but never in the abdominal parietes or elsewhere. Fibrositis might be an occasional cause for tenderness of the abdominal parietes in spite of my never having been able to recognize it. To account for many of the cases of parietal tenderness it would be necessary for the fibrositis to occur either (1) as a diffuse process over one side of the abdomen up to but not crossing the midline or (2) as a more restricted process involving every one of many adjacent nerve trunks and no other more distant trunks. One of the most common nerves to be involved in parietal tenderness is the first lumbar as manifested almost invariably by tenderness throughout its entire areas of distribution in the lower part of the abdomen, the upper thigh (fig 1) and the buttock (fig 2), implying a lesion at or proximal to its intervertebral foramen to affect both its anterior and its posterior divisions. It is not conceivable that any such haphazard processes as fibrositis and panniculitis either as diffuse or as localized lesions could consistently present these and other common clinical pictures of parietal tenderness.

Many psychologists and neurologists believe that pain and tenderness in the abdominal parietes are usually psychogenic and Pratt, Golden and Rosenthal⁴ state that they effect cures by psychology and the insertion of a hypodermic needle only or in conjunction with procaine or some innocuous solution. They are apparently much better psychologists than the surgeons who fail to effect promised cures of similar symptoms by the profound mental impression of one or more laparotomies. I have had considerable experience in injecting procaine in cases of parietal pain and tenderness and though chronic symptoms are sometimes relieved for weeks or months by a single injection, I have not seen improvement result in extensive cases other than in the restricted area of the nerves injected.

Many diagnosticians wrongly regard parietal pain and tenderness as the usual surface manifestations of visceral disease resulting from the viscerosensory reflex described by Mackenzie, Head, Sherren,⁵ Pottenger⁶ and others.

The only parietal pain and tenderness of fairly consistent type in location, size and frequency of associa-

tion with a visceral lesion of which I am aware is an area the size of a thumb nail situated in the midline about midway between the umbilicus and the tip of the xiphoid process in ulcer of the stomach or duodenum. The severity of the parietal symptoms varies in direct proportion to the activity of the ulcer. Curiously, this area does not seem to have attracted much attention from the adherents of the viscerosensory reflex. Its small size is in marked contrast to the larger areas forming the usual basis for discussions of the reflex.

It is my belief that the shoulder or scapular reference of pain and tenderness in biliary colic occurs only as an aggravation of a neuralgia, primarily due to some extraneous cause, and that the neuralgia is not cured by complete removal of the biliary pathologic changes. My experience indicates that chronic visceral lesions do not cause widespread pain and tenderness or pain that is present every waking moment over a period of weeks, months or years.

I believe that parietal pain and tenderness of the abdomen are usually due to a neuralgia and, as a rule, are independent of any intra-abdominal lesion. Spontaneous pain may be limited to a part of the abdomen in many cases in which the tenderness will be found to extend far afield. Entirely similar neuralgic pain and tenderness occur as localized manifestations in the superficial tissues of the head, neck, chest and extremities, as can be shown by pin pricking and by pinching of skin and fat alone or inclusive of muscle. Pinching is an extremely valuable but much neglected method of examination of pain and tenderness anywhere on the surface of the body. Failure to recognize neuralgia by the pinch test of skin and fat leads to many erroneous diagnoses such as aches of the brain, mastoiditis, myalgia, myositis, osteomyelitis, bone tumor, tennis elbow, mastitis, pleurisy, sprain or relaxation of the sacro-iliac joint, coccydynia, arthritis—particularly of the knee—and varicose veins. For the most part, no effort has been made to hook up these pains with a viscerosensory reflex. However, cardiologists and internists generally believe that the pains of angina pectoris are accompanied by superficial tenderness in accordance with the viscerosensory reflex. I believe their views are incorrect and I hope in the near future to collaborate with a cardiologist in demonstrating that tenderness is either absent or due to neuralgia during attacks of angina pectoris. Similar absence of tenderness in the area of referred pain occurs in so called subacromial bursitis with pain anywhere between the neck and the hand in irritative lesions of the diaphragm with pain in the supra-acromial region and its vicinity, and in ureteral colic with pain in the external genitalia. These observations indicate that pain and tenderness may not always be due to the same mechanism, a fact which seems to have escaped many clinicians.

There are a great variety of causes for neuralgia in the anterior abdominal wall or any other part of the body.¹ Any form of nerve irritation may produce neuralgia. The usual cause in chronic neuralgia is some form of spinal trouble, as scoliosis, excessive lumbar lordosis or spinal arthritis.

Chronic parietal pain and tenderness that have been present for months or years are not due to and are not cured by the operative removal of intra-abdominal lesions. As a believer in the viscerosensory reflex, Pottenger⁶ explained that the failure of recurrent parietal symptoms to disappear for months or years after subsidence of an acute visceral lesion is due to slow recovery from nerve damage. Microscopic exam-

⁴ Pratt J. H., Golden J. A. and Rosenthal Joseph. The Psychalgias. J. A. M. A. 98: 441 (Feb. 6) 1932.
⁵ Sherren J. Lancet 2: 817, 1903.
⁶ Pottenger F. M. Surg. Gynec. & Obst. 40: 62, 70 (Jan.) 1925.

mation of nerves that I excised failed to show any damage, and I prefer to regard chronic and recurrent parietal symptoms as due to extra-abdominal causes that can be relieved without intra-abdominal operations.

The diverse digestive symptoms incident to visceropositis when associated so commonly in asthenic hollow-backed individuals with chronic parietal neuralgia in varied localized abdominal areas lend further simulation to a variety of nonexistent chronic visceral lesions⁷ and are not benefited by laparotomy. I always warn the referring physician and some member of the patient's family before operation that chronic parietal symptoms will continue after complete removal of intra-abdominal pathologic changes and will require a different line of treatment for their relief. Chronic parietal neuralgia sometimes disappears spontaneously, but no more frequently with than without operation. In common with many other surgeons, I no longer operate for chronic appendicitis. Its alleged symptoms can be cured by extra-abdominal measures. The persistence of chronic parietal pain and tenderness after necessary and otherwise successful operations has given rise to common use of the opprobrious term "operative failures." Chronic parietal pain and tenderness which consistently are not cured by operative removal of organic visceral lesions certainly cannot be caused by functional organic lesions, as claimed by some internists.

Chronic parietal tenderness in the absence of spontaneous pain is a not infrequent finding in routine physical examinations in patients with spinal lesions causing mild neuralgia. I have seen many of that type who subsequently developed chronic or acute visceral lesions that ran their course either with or without operation without material change in the degree of parietal tenderness either during the illness or during several months or years following full recovery.

Chronic neuralgia may start in the chronic form but more commonly it is preceded by recurrent acute attacks which are frequently mistaken for acute visceral disease.

The three spinal conditions—scoliosis, excessive lumbar lordosis and spinal arthritis—which cause chronic neuralgia act as predisposing causes in acute neuralgia in which the exciting cause is commonly a spinal trauma or an acute toxemia from any cause such as an acute tonsillitis, an acute sinusitis, an ordinary cold, an abscess or any other acute infection.

Acute parietal pain and tenderness are usually due to acute infections that do not require operation and disappear rapidly on subsidence of the toxemia resulting from the infections. In addition to acute parietal pain and tenderness any acute infection distant from the abdomen may give rise to fever, tachycardia, leukocytosis and vomiting, a group of symptoms suggestive but far from conclusive of an acute intra-abdominal lesion, particularly appendicitis. It is a rather common experience with pathologists to find that many of the appendices removed during supposed acute attacks do not show any acute changes and therefore could not have caused the acute symptoms. In more than half of the patients referred by physicians with the diagnosis of acute appendicitis I find that the local and constitutional symptoms are due to a distant toxemia and appendectomy is not performed. The cases in

which I do not do an appendectomy are the ones that tend to develop into so-called chronic appendicitis, and there is no more need to operate in the first week than in the tenth year of their symptoms.

Acute pain and tenderness of the abdominal wall, and not infrequently elsewhere on the body surface, are caused by acute appendicitis infrequently, by acute pelvic inflammatory disease fairly commonly, and by other intra-abdominal infections rather rarely.

I believe that acute toxemia is responsible for the great majority of the cases in which acute intra-abdominal infections cause acute parietal pain and tenderness, especially when the affected parietal area lies entirely outside the Head zone for the particular visceral lesion present. A minor percentage of these patients differ from the general run in having parietal pain and tenderness localized near the site of the lesion without tenderness over the trunks of the intercostal nerves leading to the area, and in those with involvement of the lowermost part of the abdomen without tenderness in the upper thigh or buttock. Cases of this type come nearest to supporting the theory of the viscerosensory reflex, but they are not convincing and, being relatively rare, do not justify the extensive claims made by proponents of the theory. It is possible that Morley's⁸ theory that parietal symptoms are brought about by a peritoneocutaneous reflex may explain the preceding group of cases, but my studies do not permit my acceptance of the peritoneocutaneous theory for the average case of parietal pain and tenderness.

In acute appendicitis and other acute intra-abdominal lesions, Cope⁹ found that hyperesthesia might be absent or vary greatly in its position and extent, as shown by his published diagrams. In one of his diagrams a right-sided appendicitis caused mainly left-sided parietal tenderness. In my experience the great majority of quite similar areas of parietal hyperesthesia occurs in the absence of any intra-abdominal lesion. Cope records an instance of this type in his figure 19, in which anticipated cholecystitis with local peritonitis was not found at operation and the same symptoms after operation were ascribed to diaphragmatic pleurisy despite absence of friction sounds. When extensive search is made for hyperesthesia it is often found to extend far beyond the extreme limits described by Pottenger and, in addition to the abdomen and chest, it may involve the scalp, neck, arms, buttocks, thighs and, much less frequently, the legs and forearms. The wide extent of hyperesthesia, so often encountered, is sufficient in itself to negative the viscerosensory theory. The disciples of the viscerosensory reflex generally admit that arthritis or tuberculosis of the spine, various neurologic lesions and basilar pleuropneumonia may cause symptoms in the abdominal parietes quite similar to the ones they claim are produced by intraperitoneal lesions, but they offer no means of differentiation. For the most part the advocates of the viscerosensory theory are medical men; surgeons rather generally have found that the theory does not work out when checked by pathologic observations before and after operation on tenderness, which in either acute or chronic cases may persist with, or more often without, spontaneous pain for weeks or months after complete recovery from a necessary or needless operation.

Most commonly, acute pain and tenderness of the abdominal wall are not associated with an acute intra-

⁹ Cope, Zachary. *Chemical Researches in Acute Abdominal Disease*. New York: Oxford University Press. 1925.

abdominal lesion and on the other hand acute visceral lesions commonly do not cause parietal pain and tenderness. However, an acute visceral lesion and acute parietal symptoms may coexist. Acute parietal tenderness if sought for by the special tests, is easily recognized and any diagnostic difficulty that may arise is incidental to determining the presence or absence of a coexisting acute visceral lesion. When this doubt arises I abolish the parietal symptoms in the area under suspicion by injections of procaine hydrochloride—into the subcutaneous fat if the area is small, or around the trunks of the nerve supplying the area if the latter is large.¹⁰ Abolition of parietal tenderness does not cause disappearance of visceral tenderness. In the natural or induced absence of parietal tenderness I know of no better single test for acute appendicitis or other sensitive visceral lesion than to find marked palpation tenderness present over relaxed muscles and completely absent even under vigorous poking, over thoroughly tensed muscles.

My views on the treatment of parietal pain and tenderness are reported elsewhere.¹⁰ Briefly, acute neuralgia calls for treatment of the causative acute infection or spinal injury.¹¹ Scoliosis is treated by appropriate exercises and by elevation of the heel of the shoe if a short leg is found in the search that is always made for it. Parietal pain and tenderness due to spinal arthritis are promptly relieved in the majority of cases by mild irradiation of that portion of the spine from which the affected nerves emerge. Treatment of excessive lumbar lordosis by the Goldthwait special exercises to correct bad body mechanics¹² cures parietal pain and benefits digestive disturbances, although the tenderness may be slow in disappearing.

The presence of parietal pain and tenderness never excludes the possibility of a coexistent intra-abdominal lesion but the surgeon should exercise due care that a visceral lesion is present before he resorts to laparotomy.

2012 Spruce Street

ANORECTAL PAIN AND ITS CLINICAL SIGNIFICANCE

LOUIS J. HIRSCHMAN, M.D.
DETROIT

The two symptoms that usually first induce the patient to consult his physician are pain and some noticeable departure from normal in his physiologic functions. Pain is usually the symptom that induces this contact in the vast majority of cases, but apprehension and worry caused by any noticeable deviation from the normal is second only to physical suffering in causing an individual to seek medical advice and care.

Pain referred to or originating in the anorectal region usually induces the patient to seek relief promptly on its appearance. Since in most cases pain is aggravated by anorectal function and thus perforce cannot be suspended in the average case for a very long period of time, the patient who seeks immediate medical advice as a result of his disability should be the recipient of early and effective therapy.

Unfortunately, in many instances, a large group of persons will defer medical attention for the relief of symptoms referred to this region but instead indulge in self-treatment as a result of the unwarranted claims made by advertised so-called cures and specifics for all sorts of anorectal disease.

Because it is the acute symptoms that usually are noted by the patient and that cause him to seek relief the significance of acute anal pain will first be discussed. Since the sensory nerve supply of the anal canal and anus is generous while that of the ampullar or rectal portion of the lower part of the bowel is the reverse sudden or acute pain should immediately direct one's attention to the anus or anal canal.

The perianal skin undergoes a change at the line where the walls of the anal canal first appose. The glandular elements become sparse and disappear, and the skin itself thins out and the squamous epithelial cells gradually merge with and join the goblet cells of the mucous membrane. There is no clearly defined mucocutaneous juncture. The area of cutaneomucous coalescence is characterized by a transition from one type of epithelium to the other. Any lesion of the perianal or anal skin as well as the lining of the canal itself is characterized by pain, the acuteness of the pain being increased or amplified by the amount of motion of the parts.

Pain characterized by sudden onset in this region points to trauma. Overstretching of the sphincter muscle as a result of the forcible expulsion of hard, impacted or scybalous stools is one of the most frequent causes of acute anal pain. Trauma is also caused by small swallowed foreign bodies being lodged in the anal crypts.

The two next most common traumatic conditions encountered are anal fissure and acute hemorrhagic piles also improperly called "acute thrombotic hemorrhoids." Trauma caused by the faulty or careless insertion of rectal tubes and enema tips as well as that caused by clumsy or careless instrumentation in the course of a proctologic examination is merely mentioned but will not be discussed because the origin of the pain in these cases should certainly be self evident.

An individual who has become constipated or who has ingested certain indigestible or insoluble substances, such as phenyl salicylate, bismuth compounds, kaolin and barium sulphate, may suffer acute, even excruciating pain from the expulsion of stools containing substances such as these mentioned. Hard scybalous or impacted stools that are not only larger in caliber than the stools normal to the individual but as a rule are blunt instead of tapered or rounded are apt to cause overstretching and occasionally laceration or tearing of sphincter fibers in their expulsion. The muscle may be simply overstretched without there being any actual break in the lining of the anal canal, but the pain that this causes is accompanied by sphincter spasm which may last for several hours.

Anal fissure, which is also characterized by a sudden sharp onset, presents sphincter spasm as its most frequent symptom. In this case the fissure, whether produced by trauma from large stool masses or anything else that overstretches the muscle or from the breaking down of a submucous sinus is the site of pain out of all proportion to its size. The exposure of numerous sensory nerve endings produces spasmodic contraction of the sphincter and tonic spasm which resists the oncoming defecatory effort. Occasionally a fissure or splitting of the lining membrane of the anal canal will

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fourth Annual Session of the American Medical Association Milwaukee June 16, 1933.

be caused by sudden and unexpected body movement such as is produced by sneezing, coughing or undue muscular effort during bodily exercise or labor

If the patient has been suffering from an anal cryptitis or anal sinus, the thin covering of the crypt or sinus is also ruptured and a fissure will frequently be produced. Either single or multiple fissures may be produced by any of the causes mentioned.

The same causative factors may also produce a sudden rupture of some of the numerous small veins surrounding the anal canal, with extravasation into the surrounding tissues. The absorption of the liquid constituents of the blood leaves the clot, which, by its pressure on the surrounding nerve endings, causes considerable pain and soreness following the acute pain accompanying its onset.

Ulceration of the anal canal as well as of the anal crypts frequently is superimposed on the wounds caused by trauma. The frequent and erratic fluid movements resulting from hypercatharsis so weaken the mucous membrane and transitional lining of the anal canal as to render them more liable to ulceration and fissure when put to any unusual strain.

After a swallowed foreign body, such as a bit of bone, bran or popcorn, bristle shell, husk core or sharp seed, becomes lodged in an anal crypt, it not infrequently lacerates the crypt and produces symptoms of sharp, often agonizing, pain, accompanied by sphincter spasm. The inflammatory condition usually extends to the surrounding anal papillae, which become swollen, edematous and inflamed and add to the patient's misery. These are traumatized by succeeding stools to such an extent that the patient usually is forced to seek relief without delay.

While in some instances the perianal hematomas will be absorbed, in more cases the blood clot acts as an excellent nutrient culture material for infective organisms. Perianal abscess frequently follows if these clots are not evacuated.

Anorectal pain of a more gradual onset or occasionally supervening on sudden acute pain may be caused by any congestive, inflammatory, ulcerative or infective condition.

Practically every patient who consults the proctologist on account of pain of this character, or in fact any pain in the anorectal region, appears with a self-made diagnosis of "hemorrhoids." When the pain is of an acute character, even though internal hemorrhoids may be present, they may be disregarded for the moment as the cause of the acute pain. Pain, however, of a dull steady character aggravated by the passage of stools and persisting after defecation, is often produced by the presence of internal hemorrhoids. This pain may not only be evidenced in the hemorrhoidal region itself but be conducted along the sensory nerves to the sacral region and also reflexly into the groin down to the thighs.

If hemorrhoids are of the prolapsing type and become strangulated pain becomes very intense and unless relieved by the physician does not cease until the strangulation has produced a necrotic condition involving the nerve trunks themselves. Pain of this type should suggest internal hemorrhoids as its source even though the other principal symptoms of protrusion and bleeding may not be present at the time.

If the patient complains of pain that seems to increase in intensity and is accompanied by a pulsating or throbbing sensation with increasing difficulty in defecation suppuration must always be borne in mind.

Anorectal abscesses usually originate in infected crypts or from infected perianal hematomas. This type of persistent, unrelenting, increasing pain should always suggest perianal infection and suppuration. If this pain is accompanied by an increasing rise of temperature, repeated examination of the parts should be made to detect an area of induration in the anus, rectum or surrounding tissues.

It must be borne in mind that anorectal pain may be indicative of pathologic changes in other organs contiguous to or impinging on the rectum or anal canal. In the male, a posterior urethritis, prostatitis or seminal vesiculitis may all manifest themselves by pain referred to the terminal end of the bowel. Prostatic abscess is frequently prone to make its presence known first during defecation.

Vesical calculus and various types of cystitis may also cause rectal pain particularly on defecation, as well as pain radiating down the spermatic cord into the testicles.

Injuries or diseases of the coccyx or sacrum also manifest themselves by pain in this region.

In the female, disease conditions of the fallopian tubes and ovaries will not infrequently give rise to rectal pain in addition to other symptoms, and an enlarged and adherent uterine fundus, by its interference with defecation, will give rise to pain during the passage of stools. Any pelvic or uterine inflammatory condition will give rise to these symptoms, and a hypertrophied cervix not infrequently will cause pain by pressing the rectum against the sacrum, causing a definite obstruction to the fecal flow.

The pouching produced by rectocele is also productive of pain of a dull, sometimes prolonged character, particularly during the efforts to expel inspissated or scybalous stools.

Pain of a burning type as well as pruritus is frequently experienced in this region. A burning of the anus will usually follow frequent liquid defecations. These may be of the ordinary diarrheal type following intestinal upsets or acute intoxications or may be an accompaniment of the more chronic types of colonic dysfunction.

Any condition characterized by frequent fluid stools such as the various forms of dysentery or colitis, intestinal tuberculosis, or polyposis, causes maceration and denudation of the perianal integument and is productive of pain of a burning character.

Itching or pruritus ani may be produced by any of these causes and in addition may be produced by any local infection, irritation or traumatization of the perianal integument. It also may be produced by irritation from vaginal discharge or is a referred symptom from surrounding organs. A thorough search for parasitic infestation should not be neglected in the search for the cause of perianal itching. Itching of the perianal region is a subject about which volumes have been written but which must be dismissed with mere mention at this time.

The subject of anorectal pain and its clinical significance, paradoxical as it may seem must include mention of the most important disease condition that affects this part of the body, even though pain is unfortunately not an early symptom.

Of course, I refer to the presence of malignant disease. While statistics vary according to the authorities quoted, it is generally agreed that fully one half of all malignant growths to be found in the body occur in the gastro-intestinal tract and fully one half of these occur

in the large intestine. The most frequent site for the location of a malignant growth in the large intestine is the rectal ampulla. As has already been mentioned, the sensory nervous system of this part of the body is extremely meager. It is an unfortunate but nevertheless important fact that a malignant lesion may not only occur but may progress in many cases to an inoperable stage before the patient experiences noticeable pain.

Obstruction, bleeding, discharge and even a loss of weight may be noted before appreciable pain is experienced when a malignant condition occurs in the rectal ampulla. In contrast to this, any lesion, whether benign or malignant, located in the anal canal makes its presence known soon after its onset by symptoms of a decidedly painful character. For this reason, any symptoms that focus the patient's attention on the terminal end of the intestinal tract should be carefully investigated, particularly when no pain is noted.

Practically the only exception to carcinoma being the cause of symptoms not accompanied by pain is the occurrence of benign lesions in a patient who, on account of some disease of the cerebrospinal nervous system, has suffered interference with his nerve conduction. In tabetic patients this is known to occur not infrequently.

One cannot discuss the subject of anorectal pain without saying a word about some of the agents that are used to relieve pain in this region.

In the earlier days of medicine, before any of the real local anesthetic remedies were conceived and adopted, various preparations of opium were used for producing local amelioration of pain. Even today it is surprising to note the number of medical practitioners still prescribing and advising the use of the old "lead and opium wash" for external application, as well as the insertion of "opium and iodoform" suppositories for the relief of anorectal pain. The local anesthetic effect of opium is practically negligible. Far more relief can be rendered the patient suffering from anorectal pain by the use of moist heat. Heat either in the form of hot sitz baths or applied through the medium of hot compresses to the parts, is one of the best agents for the relief of pain. The inhibition of physiologic function, as far as possible, is another important factor in obtaining relief from pain in an organ whose function cannot be entirely suspended for very long.

The administration of enemas as hot as can be borne but not under any circumstances containing soapsuds affords great relief. The enema should be administered through a soft rubber catheter. Hard rubber metal or glass enema tips are under no circumstances to be used.

One of the best remedies to produce local anesthesia of inflamed or eroded surfaces is ethyl aminobenzoate. Powdered chlorbutanol and nupercaine are also valuable as local surface anesthetics. These remedies may also be administered in the form of suppositories for intrarectal pain, but, even in these instances, their anesthetic properties will be greatly enhanced by the application of external heat.

For prolonged anesthesia for the relief of pain particularly that produced by an anal fissure or ulcer of the anal canal, the subcutaneous injection of a 2 to 5 per cent solution of quinine-urea hydrochloride is strongly recommended. It must be remembered that this injection should be subcutaneous and never intracutaneous. The anesthesia produced by quinine-urea lasts from two to forty-eight hours. The use of these agents for the temporary relief of pain is for the

purpose of easing the patient's suffering while the measures for permanent relief are being planned.

Anorectal pain calling attention to the parts early, as it usually does, is a mandate to the physician to make a complete examination, not only of the anus and rectum but of all the surrounding contiguous organs, in order to discover the cause of the pain. The origin of the pain being discovered, it follows that the surgeon should carry out the indicated therapy for the relief of the condition that causes it.

In the speciality of proctology, as in the other important specialties of medicine and surgery, an early and correct interpretation of the symptoms presented is the first long and important step in the treatment of any disease and in the restoration of the patient's health.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. LIBMAN, POTTENGER,
CARNETT AND HIRSCHMAN

DR. RUSSEL S. BOLES, Philadelphia: I admit some hesitation in accepting Dr. Libman's styloid pressure test as an index of one's sensitivity. The susceptibility of the individual, the element of suggestion, and the method of approach of the examiner are such variables that it would seem exceedingly difficult to draw any conclusions from the application of such a test. Certain individuals are more sensitive to pain than others. Some believe that increased sensitivity exists in those of a neurotic nature, while others dispute this. Dr. Libman has stated that hyposensitive types show a marked tendency to feel less or none of the pain of a given disease. Specifically he mentions that such individuals may have little or no pain from ulcer of the stomach or duodenum, and that the fulness, burning or pressure that they exhibit should be interpreted as pain. If fulness, distention and pressure are due to stretching of the muscle fibers of hollow viscera as they appear to be, and if splanchnic pain is due to peritoneal irritation as many believe, it is impossible to consider these symptoms as so-called substitution symptoms for pain at least in gastro-intestinal cases. One must not let the wish be "father to the observation." Furthermore, Dr. Libman states that hyposensitive types present little or no history of an ulcer and consequently are more likely to perforate or bleed. In an analysis of twenty-four cases of perforated ulcers that came to operation in the Philadelphia General Hospital, I did not find this to be the case. With two exceptions all of these patients presented an ulcer history of a duration of from six months to thirty years. The two exceptions were mental cases. I believe that practically all ulcers produce symptoms in other words are not latent. As far as an actual acute perforation is concerned, I know of little variation in the overwhelming intensity of the pain be the individual hyposensitive or hypersensitive. Dr. Libman has mentioned contralateral pain. An occasional instance of this is cited in the case of renal colic in which the pain is on one side while the calculus is on the opposite side. With a known calculus in one kidney, the probability of another undetected calculus or some other lesion on the painful side should first be considered. In the case of appendicitis to interpret pain on the left side as a possible contralateral pain calls for a careful consideration of the associated clinical observations.

DR. BURRILL B. CROHN, New York: It has been suggested that there is considerable imagination confused with the facts regarding pain sensitivity. It is because I thought that such a comment might be made that I asked for the privilege of discussing Dr. Libman's paper so that I might again assert that the subject matter consists of more facts and less fancy, and no imagination. My experience with this algometric method convinces me that the test is reliable in the hands of any clinician who familiarizes himself with its technique and who knows how to evaluate the reaction of the patient to the pain sensitivity test. Such knowledge is easily acquired. One must remember that there are two elements in the apprecia-

tion of pain by the patient. The first is the actual physical factor, the variations in the reception of the midbrain to the afferent ascending pain stimuli. This factor apparently varies in all individuals. The second is the psychic element which steps up or diminishes, as the case may be, the expression and enunciation of the physical pain. My work has carried me particularly into the subject of pain sensitiveness in ulcer of the stomach. There must be a reason why hemorrhage and perforation so often occur as the primary symptoms in ulcer. It seemed logical to believe that the patient's low degree of pain sensitiveness explains the absence of previous symptoms of ulcer. I have a chart published which strikingly bears out this hypothesis as originally formulated. It is readily seen that, the more severe the complication is, the more likely it is to occur in a patient who is insensitive to pain. Among controls in the normal population only 11.5 per cent are insensitive to pain. One sees immediately that ulcer, even the uncomplicated types, is more likely to affect persons insensitive to pain (32.3 per cent). Hemorrhage occurs still more frequently in this type of patient, at least 40.8 per cent of all hemorrhage patients are either subsensitive or practically insensitive to pain. This figure rises to 61 per cent when perforation is considered and rises still higher to 72.7 per cent in cases of ulcer complicated by pyloric stenosis. Three patients with hour glass stomach were absolutely insensitive to pain. I believe that the degree of sensitiveness to pain affects and modifies the course of the ulcer patient. In one who is sensitive to pain who therefore diets carefully, observes precautions and constantly remembers the distress he has suffered, the course of the ulcer is likely to be more benign. The patient who is insensitive to pain is in great part unconscious of the existence of his ulcer.

DR FRED M. SMITH, Iowa City. I wish to consider briefly the clinical implications of the so called digestive form of distress. This distress is one of the most common abdominal complaints and its significance is often misinterpreted. The character of the distress varies. To some it may be a feeling of fullness, heaviness, burning, gnawing or cramplike in nature, whereas with others an accurate description is apparently not possible. The fact that the pain or discomfort is located in the epigastrium and is related to the taking of food is the most characteristic feature. For some time I have been making a careful study of the digestive distress presented by patients with peptic ulcer, malignant disease of the stomach, and various extragastric conditions giving rise to a reflex stimulation of the stomach. The mechanism of the distress so far as I have been able to determine by various means is apparently the same regardless of the underlying cause. In the past, emphasis has been placed on the relationship of the pain in peptic ulcer to meals. While in this condition the pain commonly occurs at regular intervals after meals this in itself is by no means distinctive of a gastric lesion. The significance of epigastric distress is somewhat comparable to that of the systolic apical murmur. The systolic apical murmur directs attention to the heart but there may or may not be organic heart disease. In the same manner the digestive form of distress directs attention to the stomach but unless accompanied by some distinctive feature as elicited by the history or the examination or perhaps by both there is probably no intrinsic gastric disease. It is well to bear in mind that various extragastric conditions may produce epigastric pain or discomfort of the character under consideration and that here again the diagnosis is dependent on other manifestations.

DR EMER L. EGGLESTON, Battle Creek, Mich. Dr Pottenger has again called attention to the reflex visceral disturbances of the skin areas. With this in mind one is not in such great danger of making faulty diagnoses which sometimes lead to the recommendation of surgical intervention when not indicated. For example diagnosis of a ruptured gallbladder or peptic ulcer when a diagnosis of coronary thrombosis with cardiac infarct should be made is most unfortunate. Dr Pottenger did not elaborate on the disturbances of the vegetative nervous mechanism due to anxiety or psychic disturbances. He has stressed the pain resulting from inflammatory origin but in practice one has more trouble with the purely functional symptoms than with those originating from organic cause. An undue vagus action may so disarrange the normal gastro-intestinal function as to produce symptoms difficult to differen-

tiate from organic disease. I am sure that more attention to the innervation of the abdominal viscera will present many cases drifting from the hands of physicians into the care of the irregulars. In medical thought it is difficult to leave the beaten paths. One is too prone to label the symptoms with some specific diagnosis without attempting to think rationally along the lines indicated by the symptoms. Dr Pottenger while not professing to be a gastroenterologist, has again called attention to the fact that the function of the gastro-intestinal tract is under control of the vegetative nervous system.

DR WILLIAM J. KERR, San Francisco. I have looked on pain involving the trunk as related to various sources, psychogenic pain being not so very uncommon as has been shown recently by Dr Joseph Pratt and others. Pain may be of visceral origin, related to the contraction of the hollow viscera and the various excretory tubes leading from these viscera. In patients with pain of the psychogenic type, many of the good results, obtained by surgeons and gynecologists are more or less psychogenic in nature. Proving in this case the patient has been given a very impressive psychogenic treatment. Many of the results obtained by some of the irregulars are accomplished through the influence of a strong personality or by the satisfying effect of a vigorous procedure. The viscerocutaneous reflexes are of great interest and have a distinct bearing and importance in medicine. I would not for a moment want to disagree with some of the celebrated workers who have contributed to this field but I am certain that physicians have gone too far in attributing many of the symptoms to this reflex. It is my experience that at least a third of the patients who are referred by physicians because of symptoms of angina pectoris do not have angina pectoris. In most instances they really have arthritis of the spine, scoliosis or other disturbances in the spine or the nerve roots, which give rise to referred pain in the segment. If these patients are watched over a period of weeks or months their angina pectoris is seen to go away and they develop sciatica, lumbago, or some other complication that is attributed to spinal causes. I am interested in what Dr Carnett had to say about the pinch test. I think it is of great importance in distinguishing between these various types of conditions. If the muscles of the abdominal wall are tense, it is much easier to distinguish between pain that arises in the segments themselves and pain that arises from deeper sources. I have found the variations in sensation to cotton wool and the pin to be of value in detecting disturbances in the various segments.

DR DESCUM C. MCKENNEY, Buffalo. An earlier symptom than pain, in rectal carcinoma in some cases is a feeling of weight, pressure bearing down or fullness in the rectum. In practically every case of rectal gonorrhea, especially in the female there is a complaint of frequency and burning with a blood-tinged purulent discharge, and as cryptitis, fissure and subcutaneous abscesses are prone to develop, pain may follow. Anal pockets or crypts are not infrequently the starting point of an infection that spreads in the subcutaneous tissue of the entire anal canal. Such infection makes the lining friable and easily broken during the passage of feces and accounts for recurring fissure or fissures, which produce acute pain that is followed by a more or less continuous distressing soreness. Diagnostic of this condition are the traumatic fissures showing dark thrombotic venous bases, which appear before one's eyes during even the gentlest manual eversion of the anal orifice and canal. These heal, only to recur until the cause is removed. From this source, infection may spread in the submucosa of the lower rectum and form a painful stricture. The pain of a recurring colorectal invagination or intussusception with attacks at irregular intervals extending over months or years is felt in the lower left abdominal quadrant and is in my opinion, often overlooked and mistaken for something else. When the invagination is high, the pain is felt chiefly above the pubis, but as it descends lower into the rectum it is felt in the sacrum. A pain located by the patient rather deep in the ischio-rectal fossa may be due to injury to the levator ani muscle which may be found thickened, spastic and tender (a *malgia*). Such injury may result from a fall on the buttocks. Pain that the patient locates in the end of the spine or coccyx may be caused by a posterior anal fissure sinus or infected crypt. Such a pain is sometimes cured by the linear canteri-

zation of the cervical canal and puncture of the cysts of a large cystic cervix.

DR WILLIAM BATTS Philadelphia For the past ten years I have had the opportunity of following out Dr. Carnett's ideas in examining patients. As a result of these examinations, checked by pathologic reports and operative observations, I am convinced that his interpretations of abdominal pain and tenderness are correct. The numerous viscerosensory reflexes do not stand up under critical clinical investigation as checked by surgery. The examiner will find it necessary to learn the tensed muscle test and learn to pinch so vigorously that either the patient is hurt or the examiner is compelled to quit because he has no more power, before declaring skin tenderness is negative. It is also necessary to examine for surface tenderness far more extensively than is usually done, extending the examination beyond the abdomen to the neck, arms, chest and thighs. It is likewise necessary to detect inequality in the length of the legs and to appreciate that mild degrees of scoliosis and excessive lordosis need to be recognized and corrected. The work done by Dr. Carnett offers a better explanation than any other theory for persistence of pain after operation and removes many cases from the tribulation of "operative failures" to wrong preoperative diagnosis. His test of finding tenderness present over relaxed abdominal muscles and entirely absent over tensed muscles is one of the most reliable indications for operation with which I am familiar. Many case records might be quoted in support of these facts, but the following will illustrate at least a part of them. M. S., a white woman aged 28, complained of pain in the right lower quadrant of four years' duration. Three months after the onset of the pain, an appendectomy was performed. While in bed she felt relieved but when she was up again the same distress was present. Six months later she had the right tube and ovary removed, with exactly the same result. A year later she was operated on a third time for 'adhesions,' but some pain continued. Examination revealed the operative scars with parietal tenderness over the whole right lower quadrant. There was also tenderness over the right buttock and high up on the inner aspect of the right thigh. Examination of her back revealed a right-left scoliosis, lordosis, low right shoulder and low right iliac crest. The right leg was found to be five-eighths inch short. I ordered five eighths inch to her right heel and planned on the next visit to start exercises to correct lordosis and to search for possible foci of infection. With her as with many other scoliotic patients, the raised heel gave such prompt relief that no further treatment was required. For over four years this woman has had no recurrence of her right lower quadrant pain.

DR SEALE HARRIS Birmingham, Ala. Only one of the authors mentioned the pancreas as the seat of abdominal pain. Dr. Pottenger spoke of the very intense abdominal pain in acute pancreatitis. If one will consider the anatomic relations of the pancreas, one will realize that gallbladder disease is frequently associated with pancreatic infections. The blood supply of the pancreas is such that hemic infections may occur from lesions of the intestine and colon. Allen and others think that diabetes is preceded by pancreatitis in a large proportion of cases. That certainly would make one believe that pancreatitis is a frequent condition and one that is rarely recognized. I have observed several cases of subacute and chronic pancreatitis in which abdominal pain was a prominent symptom. In one case a woman had recurring attacks of pain in the abdomen apparently due to a chronic pancreatitis. She first had a history of hyperinsulinism with recurring hypoglycemic manifestations, and later diabetes developed. In her case the pain was more over the pancreas than over the gallbladder and the Graham-Cole test showed slight impairment of gallbladder function. A youth aged 20 had recurring attacks of narcolepsy, i. e. sudden stiffening of the body and then relaxation and falling and being unconscious for an hour or two. Abdominal pain was an important factor and following his first attack he was operated on for appendicitis. The gallbladder was explored at the same time and the appendix was removed, without any relief of the abdominal pain. The attacks of pain were recurring as in duodenal ulcer or gallbladder infection. Before he came to me he had had three attacks of unconsciousness, narcoleptic attacks and the abdominal pain

was quite pronounced. His physician sent him to me with a diagnosis of probable ulcer of the duodenum. I found that he had a very low blood sugar—a typical hyperinsulinism curve. I controlled his hypoglycemic symptoms and his abdominal pain while in the hospital, with a moderately low carbohydrate and high fat diet with frequent feedings, but when he returned home his tendency to somnolence and pain recurred because of the fact that he couldn't carry out the dietary instructions and he came back and was operated on. It was expected that an adenoma of the pancreas would be found but the pancreas was apparently normal. It was decided to follow the operation that Finney, Hartman and Judd have done, the resection of a portion of the pancreas so that about half of the body and all of the tail of the pancreas was removed. All of the symptoms of hyperinsulinism subsided and the abdominal pain was relieved. He has been under observation now for ten months and his blood sugar fasting has remained normal. No pathologic condition was found to account for the abdominal pain.

DR H. L. BOCKUS Philadelphia I am one of the fortunate clinicians associated with Dr. Carnett for the past thirteen years and I want to emphasize what he has said about the importance and the frequency of abdominal pain due to other than visceral disease. I will present statistics from my office files for this purpose. Nine hundred and twenty-six consecutive office records have been gone over and in that group a diagnosis of neuralgia of the abdominal wall was made in seventy as a primary diagnosis giving an incidence of 7.5 per cent of the patients who consult me as a gastroenterologist. Sixty-four of these seventy patients were females. Scoliosis or lordosis was present in 47 per cent, and I thought that was probably the cause of the condition in that group. Arthritis of the spine was present in 20 per cent and the remainder were classified as faulty posture. Dr. Carnett will like to hear that 44 per cent of these seventy patients had had laparotomies performed without relief of this particular symptom. The location of the pain in the group was mostly in the lower part of the abdomen, mostly on the right side although there was a considerable number in which it was generalized.

DR EMANUEL LIBMAN New York In connection with my report on the occurrence of pain and gastric disturbances with calcific impregnation of the abdominal aorta, the investigations of Professor Waterston of St. Andrews are of interest. According to an abstract in *THE JOURNAL*, June 10, 1933, page 1875, he found that contact of the point of a needle with the wall of an artery elicits sharp pain and that when the point is pushed into the wall a peculiar sickening pain results with nausea and faintness. I fear that Dr. Boles has had little experience with the test. Whatever method is employed, errors can be minimized only by much experience. That contralateral pains do occur is sufficiently proved by the 'toothache on the wrong side.' Dr. Boles says that he does not believe that the symptoms which I described in connection with the stomach are often occurring in hyposensitive persons can represent pain because they result from distention. His statement really confirms my view because practically all authorities now agree that pain is produced in the hollow organs by tension, pulling and spasm. Dr. Carnett evidently misunderstood me. The mastoid process is utilized as a control for the very reason that it is normally not tender. I am deeply interested in the subject of 'pseudocholecystitis.' One of the mechanisms for its production may be explained by a recent hypothesis of mine. According to it, toxic foci (especially intestinal putrefaction) may cause hyperemia, edema (and hemorrhage) in various tissues and spasm. There is also evidence that spasm and distention may have similar effects. It is probable that gallbladders are not infrequently closed off in such ways. Of interest is the observation that a nonvisualized gallbladder may become visible following the use of mild mercurous chloride. In connection with this subject it is necessary to say a word on rebounds in the autonomic system. For example, an attack of sinusitis can cause sigmoidal spasm which in turn may set up pyloric spasm. If one succeeds in releasing the pyloric spasm (alkali carminatives) the spastic sigmoid usually relaxes and the sinusitis may improve. Many attacks of pain are dependent on the development of hyperemia especially in areas already diseased—and spasm as well as inflammatory lesions, as I have already stated, can cause such

hyperemia I believe that physicians will advance much in therapeutic accomplishment by taking these factors into consideration and studying assiduously all possible methods of influencing hyperemia

DR WALTER C ALVAREZ, Rochester, Minn I have seen many cases in which the absence of pain could be understood only after it was shown that the patient was insensitive I saw a man who complained of nothing more than severe attacks of nausea When the roentgenologists reported a large duodenal ulcer and I couldn't elicit any symptoms of ulcer I was much puzzled, but finally all became clear when I found that the man was so insensitive that he could have fourteen teeth out at one sitting without an anesthetic and without any pain I remember another man with a duodenal ulcer who got paranoid ideas three hours after meals when he should have been getting his hunger pain At those times he would get the idea that some one was following him He, too, was insensitive to pain Other such patients with ulcer complain of a gaseous distention which corresponds to the usual hunger pain One thing to be remembered is that a person can be neurotic and psychopathic and still be insensitive I agree also with Dr Crohn I think the main reason why it is so difficult to diagnose carcinoma of the stomach early is that the patients are often so insensitive that they cannot become aware of the fact that they are seriously ill I am particularly interested in the pains that have no relation to the digestive cycle, and I am disturbed over the number of useless abdominal operations performed nowadays on these patients Often the surgeon would not have operated if he had only learned first that the pain complained of was not associated in any way with the taking of food It is important also to know just where the pain is felt and if it always comes there Does it move around? Pains that move around suggest to me a functional origin Burning pains are particularly likely to be without demonstrable organic origin I think many useless operations would be avoided if more physicians knew that pain in the lower part of the abdomen is rarely a sign of disease in the upper part of the abdomen Pain below the navel is more likely to be due to a highly sensitive colon or to disease of the pelvic organs I hope that Dr Carnett's teachings will save more and more persons from needless operations

DR F M POTTENGER, Monrovia Calif After listening to the discussion, I realize that this subject needs clarification The works of Langley Gaskell Muller, Schiffl Cannon Kuntz, Higier and many others have presented a definite knowledge regarding visceral neurology which clinicians are all too slow in using for the explanation of the various reflexes met in disease One must bear in mind that the correlation of the body through the nervous system is so complete that a single afferent impulse may produce a widespread probably universal, discharge through efferent neurons as is indicated by strychnine poisoning in which sight sound smell or touch may throw the entire body into spasm In studying all phases of reflex action one must remember that different people react differently toward stimuli of a similar nature Dr Libman has given a method of measuring this as far as pain is concerned Physicians are in error in keeping their minds too much on pain Most sensory visceral effects are altered sensation rather than distinct pain The usual methods for determining changes in sensation are too gross The feather or a little piece of cotton as mentioned by Dr Kerr, will discover altered sensation better than instruments that produce greater pressure Dr Carnett doubts the nature of anginal pain and speaks of it as being a neuralgia Somatic pain and altered sensation of visceral origin are segmental in nature and their definite location is an indication that they are precipitated by the stimulus coming from the viscus itself The peripheral nerves which show sensory changes when an organ is involved can usually be shown from their origin in the central nervous system to be connected intimately with afferent neurons which supply that organ A failure to understand that chronic visceral inflammation injures sensory neurons and lowers their threshold to further stimulation is frequently the cause of useless operation and not infrequently gives both patient and clinician much concern that would be avoided if its nature were once comprehended I have had a splendid opportunity to study chronic pain in conditions of the lung and pleura Without any

increased inflammation in the viscus, patients complain of pain under conditions of depressive emotions, menstruation, weather changes and so on The recognition of this fact will help very materially in understanding some of the annoying symptoms in visceral disease

DR JOHN BERTON CARNETT, Philadelphia The papers and discussions demonstrate the widely divergent views pertaining to the subject of abdominal pain The subject demands more careful study by correlation of preoperative, operative, pathologic and postoperative observations Dr Pottenger has a better comprehension than other advocates of the viscerosensory theory in recognizing the wide extent and persistent recurrence of parietal symptoms despite operative or nonoperative treatment of visceral lesions The radical modifications that he suggests in order to make the theory fit the clinical facts however practically kill the viscerosensory theory So-called contralateral symptoms of a visceral lesion in my experience consisted of a primary complaint of parietal pain and tenderness on one side in which examination unearthed a quiescent visceral lesion on the opposite side Without exception, operative correction of the visceral lesion failed to benefit the contralateral parietal symptoms as shown by prolonged follow-up observations I am interested in another type of contralateral symptoms in which tenderness and often pain are found in a lower quadrant on one side of the abdomen and in an upper quadrant on the opposite side of the chest Without an exception thus far in dozens of cases this combination has always occurred in patients with an S scoliosis, the parietal symptoms being on the concave sides of the S curve The subjective symptom which patients describe as distention has been brought up in this symposium In my experience, so-called distention is often a symptom of parietal neuralgia The worst aerophagic gas belchers I encounter all have parietal neuralgia but ascribe their symptoms which are not relieved by use of the stomach pump to gastric distention When the neuralgia is unilateral, the patient states that the distention affects only the half of the stomach on the same side as the neuralgia, but if the neuralgia is bilateral the whole stomach feels distended Aerophagic belchers usually do not have an organic gastric lesion In the exceptional event of an organic gastric lesion being present, its correction does not cure the belching, whereas improvement or cure of the neuralgia has a corresponding effect on the belching Intestinal gas pains are likewise found in patients with parietal neuralgia and if the latter is unilateral the gas pains are usually restricted to the same side of the abdomen In closing I desire to repeat my plea for examination of all patients having abdominal pain or tenderness by the simple tests that will disclose the presence or absence of parietal neuralgia

DR LOUIS J HIRSCHMAN, Detroit Patients suffering from abdominal pain due to colonic dysfunction, on account of increased or of decreased peristalsis achieve a most astonishing measure of relief from the removal of lesions that are located in the anal canal Colonic dysfunction causes colic and extreme abdominal pain, and often such distensions caused by spasm of the musculature at the anal outlet will cause inflammatory conditions of the organs, and they will cause the opposite type of dysfunction diarrhea, followed by cramps

The Way He Walks—I need not describe to you in detail here the stamping, broad-based action of tabes dorsalis, the steppage drop-foot gait of peripheral neuritis the dragging spastic gait of the paraplegic and the hemiplegic the festinant trot of the paralysis agitans or the stiffening shuffle of old age Their enumeration however brings me to the question of how we may best train our eyes to do better as time goes by I would first of all tell you simply to make a rule of having a good look at every patient as he walks into your presence or sits or stands or lies before you To avoid embarrassment ask a question or two by all means but study him well meanwhile The art of medicine is largely the art of noticing You need to cultivate constantly both the enthusiasm and the watchful patience of the field naturalist if you wish to obtain the full value and interest which clinical work can bring—Ryle J A *The Training and Use of the Senses in Clinical Work*, *Gen & Hosp Gaz* 47 421 (Oct 28) 1933

IMPORTANCE OF THE SIZE OF STOMACH AND STOMA IN GASTRO-ENTEROSTOMIES

EDWARD L. JEKINSON, M.D.
CHICAGO

Considerable has been written during the past fifteen years on gastro-enterostomy. Much has been said about the indications, contraindications, location and size of the stoma. Straus has done some excellent work on the preparation of the stomach prior to a gastro-enterostomy.

The importance of the position of the stoma has been stressed by many writers. Many have advised that the opening be placed at the most dependent part of the stomach, while others have found that the location of the stoma was of little importance if the most important indication for the gastro-enterostomy was present, namely, pyloric obstruction. There seems to be quite universal agreement among surgeons that obstruction at the pylorus or in the first part of the duodenum is the most important indication for a gastro-enterostomy. It is in this type of case that the best results are obtained. Frequent fluoroscopic observations lead one to believe that the obstruction must be of the organic type and not due merely to spasm. If the obstruction is due to spasm the food will after the spasm has been relaxed, pass through the pylorus rather than through the stoma.

From my observations I am inclined to believe that patients with obstructive symptoms who show definite roentgen evidence of pyloric or duodenal obstruction should be placed on a strict diet, accompanied by antispasmodics to determine whether or not the obstruction is organic or due to spasm. If the obstruction is found to be organic and permanent operation may be resorted to. On the other hand if the obstruction is due to spasm further medical management should be tried and, if the residue can be greatly reduced or eliminated, operation may be dismissed or at least delayed.

For many years I have been interested in gastric retentions. Many things must be taken into account when five or six hour gastric residues are considered. It is important to consider first the habitus of the patient. Many long lean persons will show a definite six hour gastric residue with no apparent organic lesion present in the stomach or duodenal bulb. It can safely be said that these patients are not subjects for gastro-enterostomies, as other factors functional in origin may be the cause.

The residue in these patients can often be reduced by proper feeding and by support to the abdomen. Often the addition of weight by proper diet will increase the fat in the abdomen, and the stomach will be elevated and will empty quite normally.

A common observation in this type of patient is the normal emptying of the stomach, which is seen during fluoroscopic examination with the patient lying on the right side. This position certainly expedites the emptying of the stomach.

I realize that the low stomach in itself may not be the deciding factor in some of these patients. I have seen persons whose stomachs were located in the pelvis and at the six hour examination there was no residue. The low position of the stomach does not seem to be

the important factor as the cause of large gastric residues. According to my observations, the position of the pylorus and first part of the duodenum plays an important role. If the pylorus and the duodenum remain high in their normal positions there will usually be a large residue, whereas if the pylorus and the duodenum are displaced downward with the stomach there will probably not be a large gastric residue. These are anatomic variations, and the mechanics of the residue can be readily explained on this basis. Often in routine five hour fluoroscopic examinations I see rather large gastric residues, but when the stomach is filled with the barium mixture I am surprised to find that the stomach is not a low fish-hook type but is high and of the steer-horn type. Further examination adds to confusion, since no lesion can be found in the stomach or duodenum to account for the residue. For a time I reexamined these patients after they had been thoroughly atropinized, but the residue was still present and I felt that spasm was ruled out as the cause of the residue. After more investigations I learned that these patients were taking the barium meal and then were lying in bed in the dorsal recumbent position. While in this position there was a saddling of the stomach and the residue followed. The proximal half of the stomach was kept from emptying by the saddling of the lower half over the spinal column.

Other factors may play an important role in gastric retentions. First, most persons are apprehensive and the resulting stimulation of the sympathetics causes a decreased tone of the organ proper and an increased tone of the sphincter. Second, barium sulphate which is not palatable and which is not a normal constituent of the tract seems to disturb the normal downward rhythm and produces at times a feeling akin to nausea. Third, when the normal routine of many persons is disturbed as related to food taking, headache tends to develop.

Any one of these factors may be associated with delayed emptying in the absence of organic disease.

Organic lesions in the pylorus and duodenum may cause either large or small gastric residues. Frequently the residues are due to spasm rather than to scar and are relieved by antispasmodics.

If after the administration of atropine or belladonna to their physiologic limits the residue is still present, one can feel quite safe in saying that an organic lesion is causing the delayed emptying. While these drugs usually rule out the possibility of spasm they do not dispose of a rather common cause of the obstruction, namely, edema which usually accompanies the ulcer.

Often these patients are subjected to surgery, such as gastro-enterostomy, after antispasmodics have not decreased or eliminated the gastric residue. It has been taken for granted that the residue is due to an organic stricture and the functional side of the question has been disregarded.

Earlier writers such as Walton,¹ have demonstrated quite conclusively that the stoma acted chiefly as a means of drainage, and, in the presence of pyloric obstruction, the stomach contents passed through the anastomosis.

The good results reported by Walton have led others to do gastro-enterostomies for lesions without obstruction. It was in this type of case that poor results were obtained and led others to doubt whether the operation

Read before the Section on Radiology at the Eighty Fourth Annual Session of the American Medical Association, Milwaukee, June 13, 1933.

¹ Walton, A. J. The Surgical Dyspepsias. London: Edward Arnold & Co. 1930.

acted as a short circuit. Observations made by Kelling,² who did gastro-enterostomies in which all methods were used, proved that food would continue and preferred to pass through the pylorus unless the stoma was very large. The position of the stoma, whether high or low, made very little difference. If the pylorus was patent, the food preferred to pass through it. A very large stoma would serve to alter some of the flow but not the entire flow of food.

The work of Dilbert corroborated by others, showed that, regardless of when an anastomosis was made along the gastro-intestinal tract, the food prefers to pass along the normal route unless there is obstruction. Investigators working on man have shown that, provided there are no complications and the pylorus is open, the meal for the first two or three months almost wholly passes through the stoma. After the period of three months the food usually commences to pass through the pylorus.

It seems to be the accepted view that the passage of food through the stoma is dependent on the presence of pyloric spasm or stenosis.

Walton draws the following conclusions:

- 1 If there is pyloric obstruction, the food will pass through the stoma.
- 2 If there is a pyloric ulcer with stenosis, it will probably be accompanied by pyloric spasm. All the food will pass through the stoma.
- 3 If there is an ulcer on the lesser curvature the pyloric spasm will be less complete and the food will pass through the pylorus and the stoma.
- 4 If the obstruction is due to the pyloric spasm the food will later pass through the pylorus rather than the stoma.

Pyloric spasms, as a rule, are only temporary and unless there is organic pyloric obstruction the food will later pass in most part through the pylorus and the stoma will become smaller.

Gastro-enterostomies performed for ulcers high on the lesser curvature of the stomach are of doubtful value. The food usually passes through the pylorus rather than the stoma. Roentgen examination of the stomach is of great value in deciding where to place the stoma. Much of the success of the stoma in draining the stomach depends on the habitus of the patient and the position and type of the stomach.

Balfour³ and others stress the importance of a large stoma. The possibility of mechanical obstruction developing at the stoma is greatly decreased if the opening is made as large as the lumen of the jejunum. Some surgeons are of the opinion that a large stoma lessens the chance of obstruction following angulation of either the afferent or the efferent loop.

Balfour states very clearly the following:

The first and most important rule for the avoidance of failure is to be certain that the operation is needed. If there is no ulceration or obstruction at the pylorus a gastro-enterostomy is likely to make the patient worse. The second rule is that the operation be performed properly: the opening must be large; the proximal loop must not be too short and a segment of stomach surrounding the anastomosis should bulge funnel-like for a distance of at least 2 or 3 cm below the opening in the mesocolon.

Roentgen observations over a period of years prompted me to write this paper. I became especially interested in the fluoroscopic examinations of gastro-

enterostomized stomachs, first, because I felt that radiologists were not giving the surgeon or the internist as much information as it was thought they should receive and, secondly, because I was interested in the study of the stoma as to size, position and its ultimate efficiency in the drainage of the stomach.

Any one who has examined stomachs fluoroscopically is familiar with the passage of the barium meal from the cardia to the pylorus. The barium meal usually clings to the lesser curvature of the stomach for a distance of about 3 inches and then inclines toward the greater curvature in the region of the pars media and then downward to the pylorus. If the stomach is large, as in marked pyloric obstruction, the normal canalization will not take place, and the barium meal will drop at once to the most dependent part instead of being held up in the normal manner as the result of tone.

I have watched the canalization on many occasions and have thought that perhaps the best location for the gastro-enterostomy opening could be decided on during the fluoroscopic examination. If the stoma is large and is placed at the point at which the food comes in contact with the greater curvature, drainage will be facilitated.

With the usual type of gastro-enterostomy it may be difficult to outline the stoma fluoroscopically unless the radiologist is cognizant of its presence. This is especially true if the pylorus is patent. To study a gastro-enterostomized stomach carefully the radiologist should be informed that the patient has been operated on. If the radiologist knows there has been an abdominal operation, he can at least be on the lookout for a gastro-enterostomy. The most satisfactory time to study the stoma and adjacent structure is during the first swallow of the barium suspension. If the stomach is allowed to fill before the study is made, it is often difficult to obtain the desired information. The stomach will enlarge when filled with barium, and if the gastro-enterostomy is located on either the posterior or the anterior wall the opening may be obscured. Prompt examination with the initial swallow of barium sulphate I believe is the optimum time to study the stoma and small bowel adjacent to the enterostomy. The fluoroscopic study at the time of the five hour examination often gives added information as to the mobility, tenderness and presence of an ulcer crater. Frequently the exact size of the stoma can be determined at the five hour period.

My first case, in which the stomach was very large, stimulated my interest in this subject. The greater curvature was below the iliac crest and there was a definite six hour residue, about half of the original barium meal remaining in the stomach. The patient had a definite duodenal ulcer with obstruction, although it was not complete. The patient was operated on and a posterior gastro-enterostomy was performed on the greater curvature of the pars pylorica. The opening according to the surgeon, was the usual size and seemed ample.

Three weeks after the operation I reexamined the patient, the stoma was functioning quite freely and the barium was also passing through the pylorus. The bowel was freely movable at the site of the stoma. The size of the stomach had decreased probably as a result of the free drainage. Some months later the patient was again examined for a check up and a further study of the stoma. At this examination, most of the barium was passing through the pylorus. The stoma could be out-

2. Kelling, G. Zur Resektion des carcinomatoen Magen. Arch f. Klin. Chir. 229:290, 190.
3. Balfour, D. C. Results of Gastro-Enterostomy for Ulcer of the Duodenum and Stomach. Tr. Am. S. A. 45:146, 1930.

lined only by palpation and pressure and was very small. The stomach was much smaller than during the previous examination. Although the barium meal was leaving the stomach almost entirely through the pylorus, there was a moderate six hour residue.

I tried to figure the cause of the residue and determine in my mind what had occurred in this patient. From further observations of this and other cases I have arrived at the following conclusions:

The obstruction was not complete, as was shown in the original fluoroscopic examination. The obstruction present was not entirely due to the organic lesion, spasm played an important part.

The stomach was very large and low, and when the stoma was made it appeared sufficiently large. Following the gastro-enterostomy the stomach emptied freely through the stoma for a time. The tone of the stomach improved and in turn the stomach became smaller. As the stomach became smaller the stoma also decreased in size owing to contraction. While the stoma was functioning freely the duodenal ulcer improved, the spasm became less or disappeared and food again began to pass through the pylorus freely. This improvement continued up to a certain point, when the pyloric or duodenal ulcer again became active, accompanied by spasm and symptoms.

It is my opinion that if this type of patient is placed on a proper ulcer management, surgery may be avoided. If, on the other hand, medical management results in no improvement and the obstruction persists a gastro-enterostomy may be performed. If the opening is made large and the stomach is compensated, contraction of the stoma will not accompany the decrease in size of the stomach to such a point that it will not function.

I have examined a number of such cases and have found these facts to be true in patients with small or medium sized enterostomy openings.

MECHANISM OF THE DECOMPENSATION AND COMPENSATION OF THE STOMACH

Usually the normal stomach shows rather definite peristaltic waves not necessarily pronounced but in definite periods.

When the barium meal enters the normal stomach there is a certain degree of tone present and the meal is held momentarily, probably as the result of muscle tone. If the patient is of a nervous temperament, the pylorus may remain contracted for a short period. As the patient becomes accustomed to his surroundings there will follow a relaxation, and the barium will pass through the pylorus. In other patients the meal may pass rapidly to the pylorus and through the sulcus into the duodenum.

Peristaltic waves usually begin in the lower part of the pars cardiaci and pass on both curvatures to the pylorus unobstructed. While changes in the frequency and depth of the peristaltic waves are important diagnostically, it is not uncommon, in a normal stomach, to observe practically no peristaltic movements. It is my belief that increased frequency and depth of the waves is more important diagnostically than an absence of waves.

The absence of peristaltic waves is not uncommon if the patient is examined only in the upright position, the waves become more active with the patient in the recumbent position (anterior prone).

The size of the normal stomach is familiar. One forms an opinion when doing fluoroscopy as to whether

the stomach is small, large or normal. With an early lesion such as a gastric or duodenal ulcer, with no obstruction, the stomach may be small, owing to spasm and irritability. In other words it is hypertonic. During the period in which the stomach is compensating, there is no relaxation of the muscles and the peristaltic waves are usually moderately active. If the patient is not treated, obstruction may develop, due to spasm, edema or scar. Accompanying the obstruction the stomach will begin to dilate and gradually become decompensated. The muscles become fatigued, relaxed and thin. One familiar with fluoroscopy of the stomach has recorded the hyperactivity of the peristaltic waves in pyloric obstructions during the first part of the examination and, later the absence of waves, probably due to fatigue.

If the patient is operated on and a gastro-enterostomy is performed the stomach after the stoma has been made will become smaller and again compensate. If the duodenal ulcer that was causing the obstruction begins to heal and the spasm relaxes food will again pass through the normal opening. The stomach will regain its tone and become smaller. The stoma will also become smaller or as is occasionally observed become closed. The size of the stoma is very important in these cases. A good comparison is the making of a hole in an inflated rubber bladder. The hole may be 2 inches long when the bladder is inflated but will be only one fourth inch long when the air is released. I believe the same principle applies to the stoma. When the stomach is greatly dilated with loss of tone and compensation, the stoma may seem adequate but as the tone returns and the stomach becomes smaller the opening becomes correspondingly smaller and may finally fail to function, defeating its main purpose namely, drainage. If the ulcer remains healed, the chances are that no further operation will be necessary, but if the symptoms recur the stomach will again decompensate as the obstruction develops.

The preparation of the patient's stomach prior to operation in pyloric stenosis is of great importance, especially if the stomach is greatly dilated. I have observed the work of one of my associates, Dr. Grant Lang, for some time and have been favorably impressed with his method of preparation. I have had an opportunity to examine his patients fluoroscopically before and after the preoperative treatment. His reasoning certainly sounds feasible, and frequent fluoroscopic check ups have proved his contentions.

The patient is placed on small frequent feedings, and the stomach is evacuated each night. The evacuation of the stomach diminishes the secretion and as a consequence the patient is more comfortable and the stomach is under less tension.

The frequent small feedings and the evacuations tend to keep the stomach empty, and after three weeks the stomach will be smaller and there will be improvement of its tone. With the stomach improved in tone and decreased in size the anatomic landmarks are more nearly normal and the surgery is made less difficult. During the period of preoperative treatment, fluids should be given by rectum to keep up the body chlorides.

While I feel that the stoma should be large enough in every case to insure proper drainage, I do feel that there is a limit to the size of the opening. No doubt radiologists have all seen openings that have proved to be too large. In this type of case the food passes through into the small bowel too rapidly, and diarrhea

and abdominal distress follow. Another condition that is occasionally seen if the pylorus is open and the stomach is too large is the vicious circle that develops: the food passes through the pylorus and again into the stomach through the stoma.

1439 South Michigan Avenue

ABSTRACT OF DISCUSSION

DR E. P. PENDERGRASS, Philadelphia. There is one point to which I should like to call attention. Occasionally one has an opportunity in a study of a patient after a gastro-enterostomy to see the reason for the nonfunctioning of the stoma. I had a patient whom I examined in the horizontal, the right oblique, the recumbent and the prone posture, and in none of these postures did the gastro-enterostomy function. The patient was then placed in the Trendelenburg posture and the gastro-enterostomy functioned normally. The patient was very sick and because of this observation was allowed to stay in bed for two weeks in the Trendelenburg posture. Subsequently the stoma began to function normally in all positions. I think that in Dr. Kirklin's case it was the edema that prevented the gastro-enterostomy from functioning.

CHRONIC RECURRENT DISLOCATION OF THE PATELLA

WALLACE H. COLE, M.D.

AND

GEORGE A. WILLIAMSON, M.D.

ST. PAUL

Dislocations of the patella, both acute and chronic, have been known in medical writings since the earliest times, and from the time of Hippocrates to the present a rather large literature on the subject has been built up. Various classifications have been used in describing the condition, but probably the simple division into (1) acute traumatic dislocation, (2) congenital dislocation and (3) chronic recurrent dislocation seems to clarify the various types as well as any other system.

Acute primary dislocations due to severe injury are not within the scope of this paper except for the fact that such a lesion may be the actual cause and forerunner of a recurrent condition. As such it is well to remember that treatment must be prolonged and made analogous to that of a dislocated shoulder, in which recurrence also is to be feared.

Congenital dislocation from the standpoint of classification probably should be limited to those cases in which the patella is developed away from its normal position and never has been where it belongs, a family history of such a lesion frequently being present, and should not include congenital defects which predispose to dislocations as hereafter discussed. In these congenital cases the bone is practically always found on the lateral surface of the knee, resting firmly against the side of the lateral femoral condyle. The contour of the knee joint is distorted of course, and the joint function is usually very definitely decreased. The vastus medialis muscle is absent except as a flat fascial layer and a valgus of the knee may develop as the child grows older. It would seem as if normal function in a knee whose extensor mechanism was developed to the lateral side of the joint was an impossibility, and this is the rule of course, but several cases can be found in the literature in which no apparent disability

resulted. Probably the most striking case is that reported by Shapleigh of a man with congenital non-reducible bilateral dislocations of the patella who had served actively as a soldier during the Civil War with absolutely no disability from his knees. A family history of such a condition was present in this case.

The treatment of these cases differs from those in which the patella has been in or can be replaced into its normal relationship to the other joint structures, as the primary problem is to correct the dislocation, and only following this must some procedure be devised to prevent redislocation. On exposing a congenitally dislocated patella at operation it is found to be firmly held on the lateral side of the knee, and no amount of manipulation can place it in the intercondylar notch except after a rather extensive severance of the tendinous, capsular and fascial attachments on what ordinarily would be its lateral side but which is actually at the time its posterior margin, on account of its rotation of about 90 degrees. Probably the best method to accomplish this is by a long lateral incision through the component parts of the fibrous capsule down to but not through the synovial membrane of the joint. This incision may have to reach from the region lateral to the tibial tubercle to well up on the lateral side of the thigh before the patella, which is definitely underdeveloped, can be pulled to its normal position on the anterior surface of the femur. When this is accomplished, the thinned-out capsule and undeveloped vastus medialis aponeurosis, which has been stretched over the front of the knee joint, becomes very relaxed and redundant. This redundancy is used as a sling around the patella to hold it in place after the classic and highly efficient method of Krogus. This method consists briefly of making two longitudinal cuts in the medial capsule and putting the strip thus formed around the patella so as to make a sling, holding it anteriorly and preventing lateral displacement. The gap in the lateral capsule formed by changing the position of the patella is also closed by this strip from the medial side. The capsule is so thin at times that technically there may be some difficulty in separating it from the synovial membrane. This procedure seems to accomplish reduction and retention of the congenitally dislocated patella better than any other method that has ever been reported. In very young children this is probably all that will be necessary to effect a cure, except, of course, the training and physical therapy that should always follow the radical procedure. In older children it may have to be reinforced by some one of the operations described later, in order to straighten the line of quadriceps pull.

Chronic recurrent dislocations of the patella, the third type in the classification mentioned, are usually due to certain underlying predisposing causes, which may be acquired or congenital. Acute trauma may be the original etiologic factor, as mentioned earlier, but by far the majority of the cases occur without any such injury. The main predisposing factors can be listed in about their order of frequency.

1. *Genu Valgum*.—A deformity of this character angulates the line of the quadriceps pull and tends to displace the patella, which is at the apex of the angle, outward. However, the mechanism is not as simple as it at first seems, and a full discussion of it would take much more space than can be allowed here. Other factors enter into the picture and it can be argued that in many cases the valgus is a secondary growth reaction to an abnormal pull of the quadriceps.

2 *Underdevelopment of the Lateral Femoral Condyle and Lateral Ridge of the Intercondylar Notch*—Here one may also raise the question as to whether the flattening of the condyle is not a direct growth response, at least in some cases to abnormality in the pull of the quadriceps, and patellar pressure resultant on other underlying causes. As a corollary to this group are those few cases in which fractures of the lateral femoral condyle cause the same general mechanism to be developed.

3 *Relaxation of the Medial Capsule and Other Patellar Attachments*—The cases following infantile paralysis fall into this group, although some of the other underlying factors, such as genu valgum may also result from this disease. A relaxed patellar tendon is prominent in the literature as an etiologic factor.

4 *Abnormal Lateral Displacement of the Tibial Tubercle*—This finding is prominent in a high percentage of the cases and apparently may be either a congenital or an acquired defect. Certainly, when once the patella starts to dislocate, the abnormal pull will tend to accentuate this tendency, but other factors must also be present.

It can readily be seen that to separate cases of recurrent dislocation of the patella definitely into their etiologic groups is an impossibility, as all the factors may be present in any one case and the primary cause indistinguishable from others. There are a few general etiologic points that should be mentioned here although no long discussion of them is necessary. With very few exceptions all the cases reported in the literature are in the female and some authors even state that the condition is confined to girls. The three males in our small series of cases indicates that the discrepancy between the sexes may not be as marked as the literature seems to show.

In most of the cases of recurrent dislocation, symptoms first develop in the period of rapid growth between 12 and 18 years of age, although we have seen one girl of 11 years in whom dislocation of the patella would occur whenever the knees were flexed, the history showing this condition to have been present since she was about 2 years of age. The true congenital dislocations with the patella on the lateral side of the knee usually cause symptoms when the child begins to walk or even sooner, but this is of course, a different lesion from that just mentioned.

The symptoms and diagnosis of recurrent dislocation of the patella are so apparent as a rule that no discussion of them is necessary in this short paper, although much might be said about these two subjects.

It is necessary, of course, to analyze every case carefully and to reason out as accurately as possible the basic cause for the dislocation and, with this and the anatomic peculiarities before one, to mark out the proper treatment.

The question of treatment opens up a large field, and one can find in the literature in addition to the conservative methods nearly sixty different operations which have been devised to prevent and cure recurrent dislocations of the patella, and probably many more have been used without reporting. All these procedures, however, can be grouped into a few classes with basic principles underlying each group, and modifications of a technical nature do not change these principles.

The conservative treatment with special trusses and supports has never been successful as a cure and at most must be only temporarily indicated. Historically, it is interesting to recall that Hugh Owens Thomas

cured a girl with a bilateral lesion by building up the height of the lateral condyles of the femurs by weekly irritation of the bone by percussion and consequent stimulation of local growth.

The operative procedures are in the main divided into three groups:

1 Those directed toward tightening and reinforcing the relaxed structures on the medial side of the patella.

2 Those which attempt to straighten the line of pull of the extensor mechanism.

3 Those which have for their object the raising of the lateral condyle of the femur.

In the first group are those operations which tighten the medial capsule by plication or by excision of an elliptic portion, which may or may not then be used to fill in the defect in the lateral capsule which forms as the patella is moved medially. The method reported by Krogius has been referred to and its particular application to congenital dislocations indicated. Reefing and excision of a portion of the capsule are usually not sufficient in themselves to effect a cure or prevent a redislocation. The medial structures have been reinforced by transplantation of the tendons of the gracilis or semitendinosus muscles into the patella or patellar tendon, by transplanting the vastus medialis and a portion of the medial capsule into the lateral side of the patella and its tendon, and by various other combinations of muscle transplantations. For the most part, these operations are complicated and the results obtained have not been uniformly satisfactory.

Many schemes for supporting the medial capsular structures by substituting an elastic check ligament to hold the patella in its proper position have been devised. Strips of fascia lata used as free or pedunculated bands, and strands of silk have been used for this purpose. It is difficult to assign to any author the credit for the use of fascia in this manner but in this country at least, the names of Soutter and Gallie are most prominent. The former passed the fascia from the patella to the medial condyle of the tibia, and Gallie passes it to the medial condyle of the femur. In our experience, both of these procedures have been most satisfactory, the range of motion in the knee joint has not been affected and no recurrences of the original condition have been noted. The operations are ideal and seem to stand at the head of all others in this class. The isolated operations for shortening the quadriceps or patellar tendons are mentioned only to be condemned.

As an example of the result obtained by fascial transplantation, the following history is given:

A girl, aged 12 years, had had infantile paralysis five years before, which had prevented her from walking for eight weeks but which had cleared up except for some weakness in the left lower extremity. She was admitted to the hospital because of recurrent dislocations of the left patella which usually required the assistance of a physician for reduction. She had some genu valgum and relaxation of the patellar ligament. A fascial band was carried from the patella to the medial condyle of the tibia, and when she was seen two years later the motion in the knee joint was normal in its range, there had been no recurrence of dislocation, and the fascial band was holding perfectly.

A similar result has been obtained in a more recent case in which a bilateral Gallie type of operation was performed.

In the second group of operative procedures in which an attempt is made to straighten the line of pull of the extensor mechanism, both the correction of angulation due to genu valgum and the abnormal lateral displacement of the tibial tubercle must be considered. The

first operation of any type ever attempted for recurrent dislocation of the patella was a supracondylar osteoclasia performed by Guerin in 1842. Since then, osteoclasia and osteotomies have been reported by a number of surgeons as sufficient for cure, but usually the correction of skeletal alignment has had to be supplemented by some other procedure. Correction of a genu valgum deformity is still a necessary procedure at times, but we believe it will rarely in itself effect a cure and that by far the most satisfactory method of straightening the extensor mechanism is that described by Goldthwait and since modified many times. Transplantation of the lateral portion of the patellar tendon with or without the corresponding segment of the tibial tubercle, under the remainder of the tendon, to a new insertion on the medial side of the tibia has been highly satisfactory. Variations in detail, such as transference of the medial half instead of the lateral portion, transference of the entire tubercle and a number of other modifications leave the principle involved unchanged.

We have found this operation highly satisfactory, as in the following case:

A man aged 20 had been disabled for the past thirteen years by repeated dislocations of both patellas when he made any sudden twisting movements. He was able to walk quite well but was apprehensive, and instability of his gait when walking fast running, or playing games frequently ended in dislocations. Both knees were operated on, the Goldthwait procedure having been used in October, 1932, when he was last seen, in April, 1933 he pronounced himself cured. His enthusiasm over the result of the operations was gratifying. He was able to step out vigorously without fear of dislocations.

The Goldthwait operation or one of its modifications is to be recommended whenever the indications are for straightening the pull of the extensor mechanism. There is one factor, however, that must be borne in mind and that is the age of the patient. While the tibial tubercle is still cartilaginous and an intimate part of the upper epiphysis of the tibia, the possibility of interfering with the growth of the epiphysis is always present.

The third group of operations has not been as popular as those of the other two groups, as the indications are probably not so well defined. It is the aim of these procedures to elevate the lateral condyle of the femur as a barrier against the outward displacement of the patella, and surgeons have attempted to accomplish this purpose by supracondylar rotation osteotomy of the femur, by deepening the intercondylar notch, by intra-articular removal of cartilage and bone and by raising the anterior surface of the lateral condyle by an osteotomy and holding the elevated flap forward with a wedge of bone or ivory, as described by Albee, Brackett and Trendelenburg. One of the earlier attempts to prevent dislocation was by Cosma in 1865 and consisted of forming adhesions of the soft parts to the lateral condyle by the use of the actual cautery. The elevation of the lateral condyle gives excellent results in picked cases, but deepening of the notch and rotation osteotomy are not to be recommended. A brief summary of a case in which the lateral condyle was elevated, as has been described, will indicate the course of such a procedure.

A girl aged 12 years was admitted to the hospital because of recurring dislocations of the left knee since she was 3 years of age. There was a marked degree of valgus present and because of this an osteotomy of the femur was done. This did not prevent lateral displacement of the patella however and it was necessary later to raise the anterior surface of the lateral condyle as already mentioned. There has been no recurrence of the dislocation since.

SUMMARY

In the chronic recurrent type of dislocation of the patella, a combination of operations may be necessary.

The best method in our hands for reinforcing or tightening the relaxed structures on the medial side of the knee is a fascial transplantation.

Straightening the line of pull of the extensor mechanism is best accomplished by the procedure described by Goldthwait or by one of its modifications.

Raising the anterior surface of the lateral condyle of the femur is the best method for increasing the bony barrier against lateral displacement of the patella. The uses for this type of operation alone are more limited but good results are obtained in properly selected cases.

408 St. Peter Street

ABSTRACT OF DISCUSSION

DR HERMAN C. SCHUMM, Milwaukee: This paper is of particular value because it classifies and brings down to the present a subject the literature on which is voluminous. Any one who has attempted to cover this literature in recent years will appreciate the amount of work this paper represents. Every case of dislocated patella must be carefully studied in order to bring out the many etiologic factors present. When the etiologic factors are known it is not difficult to decide the best method of treatment. My experience coincides with that of the authors in that I get the best results in the majority of cases with either the Gallie or the Goldthwait type of operation. However, I feel that there is an occasional case in which a combination of methods is of importance. I should like to ask the authors how many authentic cases of medial dislocation of the patella there are. As one reads the literature one finds it mentioned, but it is difficult to find any case reports. I should also like to ask just how commonly infantile paralysis plays a part in the etiology. I do not recall seeing a case of dislocated patella as a result of infantile paralysis and I have seen quite a few cases of infantile paralysis.

DR PAUL W. GIESLER, Minneapolis: The general agreement as to the best method of treatment of this condition as well as the excellence of this paper precludes a great deal of discussion. The primary problem in congenital dislocations is the reduction and restoration of normal anatomic relations, as nearly as possible before the function can be considered and recurrence prevented. In acquired luxations the reduction is simple and the problem here is the correction of faulty functional mechanics. It is open to argument whether the knock knee and the undeveloped lateral condyle are the causes of the chronic recurrent dislocations or the result of a faulty pull of the quadriceps mechanism. The most important point brought out in this paper is to decide as nearly as possible the underlying cause for the chronic dislocation and to plan the treatment accordingly. This will consist of some or all of the following: (1) to correct a definite knock knee by casts or osteotomy; (2) to transfer the lateral half of the patellar tendon with or without its tibial attachment to the medial side; (3) further to prevent dislocation, a fascia lata check ligament between the patella and the medial condyle of the femur or tibia; and (4) if necessary an occasional raising of the anterior surface of the lateral femoral condyle.

DR JAMES A. DICKSON, Cleveland: The authors have given an excellent summary of the etiologic classification and treatment of the recurrent dislocation of the patella. They have emphasized the basic principles in its treatment rather than suggested any one particular operation. The operative treatment as the paper brought out is aimed to bring about a state of affairs that will allow the extensor apparatus to pull in a straight line and at the same time correct the relaxation of the medial capsular ligament. The operation of choice to overcome this malalignment of the patellar tendon will, of course vary with the different surgeons, some stressing the transference of the patellar attachment and others stressing the use of fascia to repair and strengthen the medial capsular ligament while others again stress the reconstruction of the exten-

nal condyle. The method of choice will depend on a complete review of the case in hand. The method that I have felt to give me the most satisfactory results was a combination of the Krogius and Gallie operations.

DR EDWIN W. RYERSON, Chicago. Years ago I did a transplantation of the tubercle of the tibia with the patellar ligament about three-fourths inch to the medial side of its original position. Fourteen years later that young woman, now grown to maturity, came back to me. During the course of those fourteen years the tibia itself had become so rotated around to the outer side that it presented a very unpleasant deformity. From that time on I have done no more of those complete transplantations of the patellar tendon and of the tubercle of the tibia. I think that this operation and all operations, including Goldthwait's ingenious procedure, should be abandoned in favor of Gallie's operation of inserting a fascial ligament to connect the patella with the internal condyle of the femur. This is mechanically correct. It will produce no rotation deformity of the tibia. It is essentially sound and I have done it a number of times with great satisfaction. In the case reported the pull of the patellar ligament was changed to the inner side and it gradually rotated the tibia round and made plastic changes that were not at all desirable. That case was a great lesson to me. There is no possible objection to the Gallie operation. It is extra-articular all the way and is mechanically sound in principle and result.

DR FRED H. ABBOT, New York. It was interesting to observe in each case the contour of the groove and the external condyle. In one case I found the groove completely filled with a markedly dome-shaped enlargement so much so that the dome had to be removed to restore the groove in order that the patella would glide up and down. There is no procedure more simple, or one that can be done any more quickly, than the raising of the external condyle of the femur by a bone graft wedge, and this has been very satisfactory in my hands. I have had a number of persons come to me in whom soft-tissue operations resulted in recurrences. The external condyle in a large percentage of cases is very much flattened. From a mechanical standpoint elevation of the external condyle restores the desired anatomy and the groove. To my knowledge I have never had a recurrence after such an operation.

DR C. A. STONE, St. Louis. I don't believe they are all due to the same cause. I questioned Dr. Ryerson to see what he thought was the cause of this distortion of the tibia, not that I objected to what he had to say. My objection to the fascial anchorage is that the fascia will stretch. I have had instances in which the fascia has stretched and a recurrence took place.

DR H. E. COOPER, Peoria, Ill. I want to place on record one case of recurrent medial dislocation of the patella. This dislocation was corrected by fastening the patella to the external condyle of the femur by means of the long perineal tendon taken from the ankle.

DR GEORGE A. WILLIAMSON, St. Paul. I am grateful for the discussion and feel that although no specific operation has been described in detail the best procedures to meet the individual anatomic factors have been mentioned and recommended. Medial displacement is apparently very uncommon. On a thorough search of the literature only one case report was found, although Janz states that medial displacement occurs in 5 per cent of cases. It is surprising that recurrent dislocations do not occur more frequently as a result of infantile paralysis. We feel that this is the most frequent etiologic factor and that the paucity of reported cases is probably due to lack of symptoms or recognition. The recommendation of Dr. Ryerson to abandon the Goldthwait operation is quite a surprise, as one bad result is not enough to condemn any surgical procedure. The entire tibial tubercle should not be transplanted as there is danger of losing the function of the extensor mechanism if any accident should occur. We have not experienced any recurrences due to stretching of the fascial transplant in the Gallie or Soutter operations and I firmly believe that any slipping that takes place is in the suture lines and not in the substance of the fascia.

BRONCHIAL ASTHMA AS A COMPLICATION OF PREGNANCY

BRADFORD GREEN, M.D.

Assistant Obstetrician to theankenau and Germantown Hospitals
Instructor in Obstetrics Temple University School of Medicine

PHILADELPHIA

Bronchial asthma as a complication of pregnancy would seem to be found rarely, since a review of the literature from 1920 reveals a remarkable paucity of information on the subject. It is noteworthy that most of the work reported has been published in foreign medical journals and, in a few cases, subsequently abstracted in the American journals.¹ It will therefore be of value to put on record the two cases reported herein and give a brief summary of the condition and the accepted views as to the prognosis and treatment.

The bronchial asthma occurring during pregnancy may be divided into two separate and distinct groups, namely, those in which a previous history of asthma can be obtained and those in which the asthma seems to be a direct result of the sexual cycle or pregnancy. Group I includes those in whom the asthmatic attacks are directly traceable to sensitization to pollens, proteins or some focus of infection in the body, such as the teeth, tonsils and sinuses. In these patients a history of asthma antedating the pregnancy can usually be obtained, although occasionally the attacks make their first appearance during gestation. When they are encountered during pregnancy, the attacks are of much greater severity than usual, often reaching alarming proportions and terminating in the death of the mother or the fetus or both. two cases in which death occurred during an asthmatic attack, one of the present cases terminated likewise. The question of therapeutic abortion or induction of labor often comes up in this type of case, but the consensus is that the asthmatic condition should be treated, per se, and the coexisting pregnancy ignored entirely.¹

Group II presents a varied and interesting series of cases in that the asthmatic attacks appear to be the direct result of malfunction of the female genital system.⁴ The cases can be divided into subgroups, as shown in the accompanying table. In the first of these, the asthmatic attacks start with the menarche and recur with each succeeding menstrual period. Very often the attacks cease during pregnancy and lactation only to recur on reestablishment of the menstrual cycle. It is likely that these attacks are precipitated by some of the hormones produced during the menstrual cycle or are due to absorption of some of the products of the uterine cavity during the phase of endometrial disintegration.⁵

In another subgroup the asthmatic attacks are seen during gestation and lactation only. No history is obtainable of attacks antedating the pregnancy or after the termination of the pregnancy and lactation. Such cases are rare and when they do occur indicate a sensitivity to some specific product eliminated by the embryonic tissue.⁶ This group is the only one in which therapeutic emptying of the uterus would be warranted.

Bronchial Asthma During Pregnancy

in the hope of relieving the asthmatic condition. Occasionally, this group is found to subdivide into cases that show the asthmatic attacks during a pregnancy with a male fetus, with complete absence of attacks during gestation with a female fetus, and vice versa. It is possible that in such cases the factor responsible for the attacks comes from the developing sexual organs of the fetus. That such a factor exists has been shown by the experiments of Dorn and Sugarman,⁷ in which the sex of the fetus could be predicted from the reaction caused in immature male rabbits by the injection of the mother's urine.

Several interesting facts as to the prognosis in the child have been brought out by a follow up of these asthmatic cases.² Fifty-eight per cent of the children from group I in which the mother had preexisting asthmatic attacks showed some form of allergic reaction before the age of 10 years. In cases in which the father also exhibited some type of sensitivity, this rose to 72 per cent. The most interesting observations in the children of mothers catalogued as group II are in those in which male or female pregnancies only produced the

attacks. The children who had caused attacks while in utero almost invariably had some type of sensitivity themselves, while their siblings of the opposite sex were not affected.⁸

Two histories of patients with bronchial asthma during pregnancy are submitted. Both belong to group I, but the first should be included in subgroup 1 and the second in subgroup 2.

REPORT OF CASES

CASE 1—A woman aged 22, in November, 1930, a few months after the birth of her first child, had a severe attack of bronchial asthma, which all medications except morphine failed to relieve. She was admitted to the Mount Sinai Hospital with a history of attacks of asthma for seven years, beginning at the age of 15. The interval between attacks, in 1930, had lengthened to about eight months.

A roentgenogram of the sinuses after admission showed that the frontals were absent and the maxillary sinuses small and symmetrical and both slightly cloudy, the sphenoids and ethmoids displayed no abnormality. A submucous resection was performed under local anesthesia while the patient was in the hospital. A roentgenogram of the chest showed no evidence of consolidation or effusion but considerable congestion in the left lower lobe and marked fibrosis radiating from the right hilus region downward to the right lower lobe and probably an associated bronchiectasis.

The blood count revealed 80 per cent hemoglobin, 4,280,000 erythrocytes and 19,000 leukocytes. The blood urea nitrogen was 17.8 mg per hundred cubic centimeters of blood and the blood sugar 101 mg. The Wassermann reaction was negative and a blood culture yielded no growth.

A diagnosis was made of bronchial asthma of infectious origin, associated with moderate allergic reaction and sinusitis. After discharge, the patient continued attending the allergic clinic of the hospital and was given injections of dust vaccine with good results.

Nov. 29, 1932, then 24 years of age and in the eighth month of her second pregnancy, the patient had an acute and very severe attack of asthma, followed in a few hours by another attack, and was brought to the Lankenau Hospital. She was cyanosed with respiratory discomfort answering questions with difficulty and with an expression of despair. Sedatives were administered and after a time she appeared comfortable.

The lungs showed impaired resonance throughout and distinct prolonged expiration accompanied by many wheezing musical rales. Inspiration was free and rather of the bronchial type. Tactile and vocal fremitus was increased throughout. The mucosa of the nose was injected and there was some nasal discharge. The pharynx was injected.

The cardiac outline was normal, the sounds were rapid and distinct with a blowing systolic murmur of functional nature. The abdomen was distended and the fetal heart sounds could be heard.

The urine was clear yellow, acid and of 1.011 specific gravity and showed a very faint trace of albumin, a slight trace of acetone, mucus, epithelial cells and urate crystals. The blood count revealed hemoglobin, 70 per cent, 3,740,000 erythrocytes and 16,500 leukocytes, with 64 per cent neutrophils, 30 per cent lymphocytes, 5 per cent large mononuclears and 1 per cent eosinophils. The blood urea nitrogen was 10 mg per hundred cubic centimeters of blood and the blood sugar 95 mg.

The following day, at noon the patient had another acute attack and became irrational. Sedatives were given with good effect. She perspired freely, the color improved and the pulse was good. Toward evening there was a second attack. The patient became cyanosed and started screaming, but under medication the condition abated and she rested comfortably during the evening.

The next day, December 1, she had another paroxysm, the irrationality continued, and a few hours later she became violent screaming and swearing. By noon she was definitely cyanosed and was unaffected by drugs. Since the patient was eight months pregnant a consultation was held relative to

emptying the uterus. It was decided, however, that the shock would be too great. Oxygen was administered and the color improved, but the patient continued in her irrational state and died at 6:30 p. m. The advisability of a postmortem caesarean section was considered to save the child but, as it was scarcely viable and the family objected, the operation was not performed.

The systolic and diastolic blood pressure readings in this case while in the Lankenau Hospital were 130/85, 140/70 and 135/95. The temperature, November 29, was 97.8 F., on the 30th it ranged from 98 to 99.2 and, December 1, from 99.6 to 108 just before death.

It is of interest that although this patient had been subject to asthmatic attacks since she was 15 years of age, none occurred during the entire course of her first pregnancy. From this point of view, the case would seem to fall in group II, but the infective foci and the later history suggest that it should be included in group I subgroup 1.

A summary of this case leads one to believe that death was due to the chest complication, that is, to the asthma and that the pregnancy was but an exacerbating cause of the asthmatic condition. The maternal symptoms are difficult to explain either from an asthmatic standpoint or from that of a toxemia of pregnancy. The urinary conditions, the blood pressure, the blood urea and the differential leukocyte count all tend to discount the possibility of a toxemia of pregnancy of a degree sufficient to cause such violent symptoms.

An attempt to empty the uterus, by either the abdominal or the vaginal route, had little to offer in the way of decreasing the severity of the asthmatic attacks and any operative delivery would probably have taken away whatever chance the woman had for surviving. In other words in this case the pregnancy could be disregarded since any hope for the survival of the patient lay in her response to treatment for the asthma. Whether or not the prolonged anesthesia induced by colonic administration of ether, as advocated by Mavtium⁹ would have saved this patient is a question but in another case of the same type and severity this mode of treatment should certainly be given a trial.

CASE 2—A quinquagena aged 32, admitted to the Germantown Hospital, complained chiefly of dyspnea, gain in weight and absence of menses.

Menstruation had begun at 14 years and was regular until seven years previously when the patient first began to increase in weight. Since then she had had one period a year until thirteen months before admission, and none since, she had gained 30 pounds (13.6 Kg.) in the last year.

The history showed that the tonsils and adenoids and the appendix had been removed and that the patient was subject to attacks of dyspnea which tended to disappear suddenly. She stated that she had had "chronic bronchitis" for several years, which had been worse during the summer months. For six or seven weeks previous to admission to the hospital, the patient had had a persistent cough with expectoration of thick greenish mucus but no blood. At times the dyspnea became quite severe and the patient perspired freely. More recently she had had headaches, spots before the eyes and occasional edema of the lower extremities. Her appetite had been good and the bowels regular, and there had been moderate frequency of urination and nocturia.

On physical examination, the patient coughed a great deal and appeared anemic and dyspneic. The head, eyes and ears were normal, many teeth were missing but the rest were in good condition. The tongue and throat were normal and no tonsillar tissue was seen. It was noted that the neck was full, but the thyroid could not be felt. The chest was symmetrical and well developed with no depressions. Expiration was prolonged. On auscultation many wheezes and musical rales

could be heard over the entire chest but were more prolonged at the bases anteriorly. The voice sounds apparently were not changed. The heart sounds were poorly heard owing to the thickness of the chest wall, but no gross murmur was evident. The blood pressure was 130 systolic, 80 diastolic, the pulse was regular, beating at the rate of 96 per minute. The abdomen was pendulous with a scar over McBurney's point, and generalized tenderness was present over the entire lower portion. The liver and spleen were not felt but a mass 3 or 4 inches in diameter, smooth, round, firm and freely movable, was thought to be palpable in the right lower quadrant. The extremities showed slight varicosities and edema with normal reflexes. A provisional diagnosis was made of bronchial asthma, obesity and probable ovarian tumor.

The asthmatic attacks continued in spite of the administration of epinephrine or morphine. No areas of dullness could be found on percussion although many fine asthmatic rales persisted throughout. There was some vomiting and diarrhea with the more severe attacks, but less cough than when the asthma was mild. The surgeons believed that an ovarian cyst might be the predisposing factor for the asthma and an exploratory laparotomy was advised. The presence or nonpresence of pregnancy could not be definitely determined.

At operation the uterus was found extending to the rib margin with a fetal body palpable through the uterine wall, so the abdomen was closed without further surgery. Post-operatively the patient had gas pains and vomited, but in general she had a good convalescence.

Laboratory examination showed urine with a specific gravity varying from 1.010 to 1.030, negative albumin until just before discharge when a trace was noted. Hyaline casts on one test, and occasional leukocytes, squamous epithelial cells and amorphous urate crystals. The blood picture showed hemoglobin, 82 per cent; erythrocytes 4,100,000 and leukocytes, 8,000 with 73 per cent neutrophils, 18 per cent lymphocytes, 8 per cent large monocytes and 1 per cent eosinophils. The blood urea nitrogen was 77 mg. per hundred cubic centimeters of blood and the blood sugar was 87.2 mg. Both the Wassermann and Kahn reactions were negative. The basal metabolic rate on three occasions varied from plus 3.1 to plus 22.3 per cent.

Röntgen examination of the chest showed no pathologic changes. A roentgenogram of the pituitary gland was negative except for a posterior lip that was slightly longer than usual. Examination of the sinuses was negative but one of the maxillae showed bone destruction from pyorrhea, though with no apical infection.

Protein sensitization tests showed that the patient was susceptible to the following foods: cow's milk, 1 plus, cod fish, 2 plus, tuna fish 1 plus, turkey 1 plus, carrots 1 plus.

The patient was discharged from the hospital and was treated in the prenatal clinic for the following three months, she then was readmitted to the hospital in labor and was delivered, without any untoward effects, of a male child weighing 8 pounds 4½ ounces (3,756 Gm.). She was kept in the hospital for fourteen days post partum during which period the temperature at no time was elevated above 99 F. and she had no asthmatic attacks although previous to delivery the attacks had been continuous since discharge from the earlier admission.

Fifteen months later the patient was again sent to the hospital with a history of two attacks of asthma a night for the past two months, relief from which was usually obtained in from two to three hours with medication. She had had no menstrual period for the past three months.

Physical examination showed generalized squeaking rales in the thorax and a slight cough, vocal fremitus was good and the breath sounds were fairly good over the back. Otherwise the examination was negative. The laboratory reports were similar to those obtained on the previous admission except that a blood count showed 2 per cent eosinophils and blood epinephrine of 3.1 per cent. The basal metabolic rate varied from minus 20 to plus 28 per cent. A phenolsulphonphthalein test revealed 45 per cent elimination in two hours. Electrocardiographic examination proved the heart essentially normal.

During the stay in the hospital the patient was treated with epinephrine, ephedrine, potassium iodide and thyroid extract plus the usual sedatives, laxatives and the like. On discharge, the attacks had decreased both in frequency and in severity.

⁹ Mavtium, C. K. Relief of Prolonged Attack of Bronchial Asthma by Colonic Administration of Ether. *Clin. North America* 15: 201 (July) 1931.

An analysis of this case indicates that for several years previous to the first admission to the hospital the patient had a mild degree of asthma which was not sufficiently severe to require medical intervention, but that with the onset of pregnancy the asthmatic condition became more pronounced. Although delivery gave relief for a few months, the asthma has now become a specific entity and is not affected by any obstetric condition. Here a marked endocrine dysfunction is apparent, but the patient is also definitely sensitive to exogenous influences, and the case appears to fall in group I, subgroup 2.

CONCLUSIONS

1 In a patient with true bronchial asthma of anaphylactic origin, the attacks are markedly exacerbated by pregnancy and the outlook can become alarming.

2 In the type of bronchial asthma which is directly related to the sexual cycle, the attacks may appear with each menstrual period, be absent during pregnancy and lactation, and then recur with the reestablishment of the menses.

3 On the other hand attacks may occur only during pregnancy or even only during pregnancy with one sex and not with the other.

4 The attacks are occasionally associated with a mild toxemia and are relieved when the toxemia is cleared up under conservative treatment.¹⁰

5 Treatment consists of combating the asthma and disregarding the pregnancy.

6 Termination of pregnancy at best assures only the pregestational state.

7 When the attacks are not accompanied by toxemia but are due specifically to pregnancy, therapeutic abortion might be warranted in extreme cases.

8 Attacks of bronchial asthma are a decided menace to the welfare of the fetus.

AMEBIASIS

INCIDENCE IN PRIVATE PRACTICE

H. S. SUMERLIN, M.D.

SAN DIEGO, CALIF.

Most of the published reports on the incidence of human intestinal protozoa in the United States are based on studies of patients in charitable institutions, that is, indigent persons. The present survey is offered to show the incidence of intestinal protozoa in individuals of a higher social status. It is a summary of the results of routine examinations of the stools of 1852 patients from the private practice of the Rees-Stealy Clinic during the past four years. With the exception of an insignificant number of Mexican families of the better class the material for this study came from American homes of San Diego city and county.

This study was not limited to patients with gastrointestinal complaints. Many of these examinations formed a part of the routine general examinations of patients with more or less indefinite symptoms and the results therefore constitute a fair estimate of the incidence of protozoa in general private practice.

Patients were given printed instructions regarding the obtaining of the specimens and were asked to sub-

mit three fecal specimens on consecutive days. The first, a liquid specimen, was collected in the laboratory following a saline cathartic. This was kept in a warm cabinet until the examination was completed. Subsequent specimens were brought to the office in paraffined paper cartons. A number of patients failed to submit the desired number of stools and in some cases only one specimen was obtained.

For the detection and identification of protozoa, a combination of the cover-glass preparation in physiologic solution of sodium chloride and a modification of Donaldson's iodine-eosin mixture¹ was employed. At first, permanent preparations stained with Haidenhain's iron-hematoxylin were used. It was soon found, however, that it was not necessary to resort to this procedure except in rare instances. In many specimens in which there were only a few parasites it was our experience that all the protozoa disappeared from the slides during the iron-hematoxylin staining. Further-

more, these preparations rarely disclosed parasites that had not been previously detected. This has been the experience of other workers also. With the iodine-eosin mixture properly adjusted, the cysts appear as bright yellow circles in a red field, the flagellates and motile amebas stained red. The oil immersion objective was used to study the internal structure. In almost every case the cysts of *Endamoeba histolytica* can be identified in the cover-glass saline solution preparation by their large highly refractile chromatoidal rods. The identification of motile forms is frequently difficult. Good illumination is absolutely essential and we are using with satisfaction the Bausch and Lomb adjustable microscope lamp with a Corning Daylite glass.

The results of the examinations in the cases of 1,339 adults and 513 children are given in table 1. The cases in children are listed separately to show the low incidence of protozoa as compared to adults. *Endamoeba histolytica* was found in thirty-one adults, or 2.3 per cent, and in two children, or 0.4 per cent. Combining these results gives an incidence of 1.7 per cent. In three of our adult cases the infestation undoubtedly occurred outside the United States, as two cases were from families of United States naval officers who recently had returned from the Orient, and the third case was that of a missionary who recently had returned from India. If these cases were not included, the incidence among the adult permanent residents would be reduced to 2.1 per cent. In this series only one case of frank amebic dysentery was encountered and that was in a 5 year old child. In only four cases were cysts absent from the stools.

1 Saturated solution of eosin in physiologic solution of sodium chloride 1 part 5 per cent potassium iodide in physiologic solution of sodium chloride saturated with iodine 1 part physiologic solution of sodium chloride 2 parts. These solutions are kept in separate dropping bottles and mixed fresh daily.

¹⁰ Williams J. W. Textbook of Obstetrics. New York: D. Appleton & Co.
From the Rees-Stealy Clinic.

Table 2 compares the results of this survey with surveys made elsewhere. The incidence of *Endamoeba histolytica* varies from 0.2 to 15.58 per cent in the different studies. There is no doubt that the incidence varies with the class of patients and the geographic location. One cannot but wonder why, in view of the large number of people harboring this parasite, so few cases with frank amebic dysentery are seen and why there are not more local epidemics like the recent outbreak in Chicago.

It has been stated repeatedly that a single fecal examination will reveal only about half the protozoa that can be detected by multiple examinations. This has not been our experience as is shown by table 3, which is an analysis of the positive cases. In the thirty-three cases of infestation with *Endamoeba histolytica*, the parasite was found in the first specimen in thirty-one cases, in the second in one case and not until the third examination in one case. The fact that the first specimen was collected following a saline cathartic

NUTRITIONAL NIGHT BLINDNESS

REPORT OF A CASE

DWIGHT L. WILBUR, M.D.

AND

GEORGE B. EUSTERMANN, M.D.

ROCHESTER, MINN.

Night blindness, sometimes called hemeralopia or nyctalopia, which is a difficulty in adapting, or an inability to adapt the faculty of vision to very faint illumination, may result from nutritional deficiency as well as from intra-ocular disease. It was recognized at the time of Hippocrates that liver or liver and honey was a cure for night blindness. In the past few years, experimental and clinical evidence have demonstrated that night blindness caused by faulty nutrition is the result of deficiency in vitamin A and is not infrequently the first manifest symptom of such deficiency.

probably explains these results. We found, however, that in some cases subsequent examinations revealed other species of protozoa not found on the first examination.

SUMMARY

1 During four years, a survey for human intestinal protozoa among 1,852 private patients was made. The incidence among 1,339 adults and 513 children was noted.

2 The incidence of *Endamoeba histolytica* among 1,336 adult permanent residents of San Diego city and county was 2.1 per cent, and among 513 children was 0.4 per cent.

3 A single fecal examination will reveal the protozoa actually present in over 90 per cent of the cases, if a liquid specimen is collected following a saline cathartic and examined while warm.

The most familiar form of deficiency of vitamin A, xerophthalmia, both of infants and of adults especially the latter, is extremely rare in the United States. This is largely because vitamin A or its precursor, carotene, is widely available in foodstuffs, and the body ordinarily stores large quantities of this substance, a fact not true of some of the other essential foodstuffs. Although nutritional night blindness is not uncommon in the Orient and in some European states, it probably is extremely rare in this country and there are few if any authentic cases reported as having occurred in the United States.

Disease caused by deficiency of vitamin A may result (1) from reduction of adequate intake of vitamin as the available food supply may be poor in it, (2) from deficient absorption and storage as the result of intestinal or hepatic derangement or disease, (3)

From the Division of Medicine, the Mayo Clinic.
Since submission of this paper for publication, our attention has been called to a report of a case of night blindness due apparently to vitamin A deficiency, presented by Dr. D. I. Filderquist of Duluth at the meeting of the Minnesota State Medical Association in May, 1933. The report of this case, which was observed in 1927, will be published in Minnesota Medicine.

from altered metabolism of the vitamin in the body,³ and (4) from the increased demand for and consumption of the vitamin, for example during periods of rapid growth, pregnancy or disease, especially during severe infectious diseases when the basal metabolic function may be greatly enhanced. McCollum and Simmonds⁴ have emphasized the fact that it is doubtful whether a deficiency disease ever occurs uncomplicated in man or in animals and that deficiency diseases, with the possible exception of scurvy, can be produced as uncomplicated syndromes only by carefully planned experimental diets.

The versatility of vitamin A has only recently been appreciated. A remarkably increasing literature, which we recently reviewed, testifies to its growing importance in the chemistry of food and nutrition, not only in the prevention and cure of certain ailments of man but when supplied in liberal proportion, in the maintenance of a satisfactory state of nutrition and a high degree of health and vigor, both in the growing child and in the adult.

Because of the extreme rarity of case reports of nutritional night blindness occurring in the United States, and in order to emphasize the fact that even though the daily intake of an individual is adequate, a state of nutritional deficiency may result, the following case has been thought worthy of presentation.

REPORT OF CASE

A man, aged 48, a civil engineer, registered in the clinic June 5, 1933, because of diarrhea of two years' duration. Since the age of 18 years he had had symptoms of duodenal ulcer, for which gastro-enterostomy had been performed at the clinic in 1919. Ten years subsequently, symptoms of jejunal ulceration developed and two years thereafter symptoms of gastrocolic fistula appeared. During this period of two years he had continued on a diet which was quantitatively and qualitatively adequate for proper nutrition. In the course of the diarrhea he had passed from four to six liquid or soft stools daily and the stools often had contained undigested particles of food. Physical examination at the time of admission in 1933 revealed a general cachectic state, which will be considered subsequently. Surgical repair of the gastrocolic fistula was performed early in June, and from this surgical procedure the man made an uneventful convalescence.

The first symptoms of night blindness had developed about April, 1932, one year after onset of the diarrhea. The patient, who because of his gastro-intestinal disabilities had not done any work since 1928, had become interested in the discussions regarding a municipal power plant in the small city in Missouri where he resided. One of the reasons for his interest was that the street lights had appeared amber colored and dim, and he had also noted that the lights in his house were dim. He had complained bitterly about this for some time before he had appreciated the fact that the trouble was his inability to see the lights as well as formerly. In the daylight he could see satisfactorily. In June, 1932, he had attended a fish supper, and about 8 o'clock in the evening when it had become dark, he was unable to get around satisfactorily and walked over the grates where the fish were being cooked, burning his feet in the coals and stumbling over several objects. Since that time he had noted that on coming from the bright outdoors into the house, he would be unable to see details for about five minutes. If there was a clock or a picture on the wall he would be unable to tell the time and unable to distinguish the details of the picture for

about five minutes. One evening, when coming out of church, the exit from which was very brightly lighted artificially, he had bumped into several people without realizing that any one was in his way until he came in contact with them. He had had similar experiences on the street at night. He had fallen over steps which he did not see and at one time he had tripped over a dog, which was sleeping in his pathway. One of the greatest difficulties he encountered was driving a car at night. He usually was able to do this by focusing on a light in the distance, but by so doing he was unable to tell whether he was on the shoulder or on the wrong side of the road. If he put on the dimmer lights, which would illuminate the street directly in front of the car, he was able to get along fairly satisfactorily. Although he had driven into the driveway leading to his garage many hundreds of times, he had a great deal of difficulty in finding the driveway and on one occasion drove up onto the lawn and to the front steps of his neighbor's house.

The night blindness occurred periodically. As a rule, the patient had periods of from two to three days to seven to ten days in which the night blindness was present with free intervals between of from one to four weeks. There was no apparent cause for the exacerbations or remissions of symptoms. In addition, the onset of a period of night blindness was usually slow, occupying from one to three days, usually the latter, whereas the attack usually subsided in one day. Peripheral vision seemed somewhat better to him than central vision.

Since the time of the repair of the gastrocolic fistula there has been complete freedom from night blindness, and this has been the longest period of freedom from the disability since its onset. At the time of the patient's dismissal from the clinic, five weeks after operation, his weight was 6 pounds (27 Kg.) lower than before operation but diarrhea and abdominal symptoms were absent and his diet was satisfactory.

Ophthalmologic examination made by Dr. W. I. Lilje, post-operatively, disclosed the following: The pupils reacted normally, the media were clear, and the fundi were normal except for mild sclerosis of the retinal arteries. Presbyopia was present. The perimetric fields were normal.

For two years the patient had lived on a generous diet which contained reasonably large quantities of milk, butter and fresh vegetables, and he ate rather large amounts. At no time during this period did he exist on a diet which in any way could be said to be low in vitamin A or its precursor, carotene.

COMMENT

The physiologic changes accompanying the development of nutritional night blindness are remarkable. They depend on a disturbance in the metabolism of visual purple of the retinal rod cells, which have to do with vision under faint illumination. Under ordinary circumstances of bright light visual purple is bleached but it is also constantly being regenerated. Experimental evidence indicates that there is a close relationship between vitamin A and the visual purple, since Fridericia and Holm⁶ have shown, and Tansley⁷ has confirmed quantitatively that there is delay or failure in regeneration of visual purple of animals that are deprived of vitamin A. In addition, the high vitamin A content of the hog's retina has been demonstrated by Yudkin, Kriss and Smith.⁸ It is possible that in the retina there may occur a reversible reaction, vitamin A being required for the production of visual purple, and the latter, under suitable conditions, producing vitamin A. It is obvious that manifestations of night blindness will occur chiefly after exposure of the patient to bright light for it is in this way that the supply of visual purple is depleted and ample regeneration can-

not occur. This has been convincingly demonstrated by Aykroyd,⁹ who found that, after prolonged exposure to brilliant sunlight with apparent rapid depletion of the visual purple, night blindness in several cases, first developed.

Night blindness may be the result of such intra-ocular diseases as retinitis pigmentosa, optic atrophy, glaucoma and choroiditis, or the disability may be congenital. In the absence of evidence of intra-ocular disease, as in the case reported, night blindness is of the essential type and is usually considered to be the result of nutritional disturbance. There are several factors in the present case which are worthy of note. There were two atypical features. First, the patient regarded the lights at night as amber colored and second, the night blindness was intermittent. It is possible that the second factor may be explained on the basis of a very close balance between supply and requirements of vitamin A. During the periods of night blindness a negative balance may have existed and then during periods of remission a positive balance may have been present. That very small amounts of vitamin A will relieve night blindness of patients has been demonstrated by Spence who eradicated this symptom in from twelve to thirty hours by the administration of one or two small doses of cod liver oil.

It is exceedingly important to note that the dietary intake was apparently adequate. Nutritional deficiency, therefore, is to be explained largely as the result of the presence of the gastrocolic fistula which allowed food to pass into the colon from the stomach preventing proper and adequate digestion and assimilation. Evidence that a state of malnutrition was present included the cachectic appearance of the patient, the moderate loss of weight, the occurrence of repeated cutaneous infections, and the presence of true cachecticorum as well as the night blindness. Spence has noted nutritional night blindness in cases in which patients apparently were well nourished. The only other physical evidence present that might have been the result of deficiency of vitamins was caries of the teeth. This symptom has been shown to accompany deficiency of vitamins A, C and D. The disappearance of the night blindness in the case reported, is a result of surgical repair of the gastrocolic fistula and the resultant cessation of diarrhea is another link in the evidence that this symptom was the result of nutritional disturbance. Direct proof that the night blindness was caused by deficiency of vitamin A would have been furnished if parenteral administration of the vitamin had successfully relieved the symptoms. However it cannot be denied that actual proof of such relationship has not been established in this case. The evidence although good, is circumstantial and presumptive.

It is conceivable that, with the widespread use by experts of methods for the detection of night blindness numerous instances of such inability to adapt the vision in part or completely to faint illumination will be noted in this country. Care must be exercised in ascribing such changes to deficiency of vitamin A. It should also be emphasized that clinicians must be on the alert for latent and actual dietary states of deficiency among patients with organic and even functional gastro-intestinal disturbances. Despite an apparently adequate diet, the presence of derangement or disease interfering with normal digestion and assimilation, as in the case reported, may be the underlying factor in

the production of a state of deficiency. General recognition of this fact is highly desirable.

Our interest in disorders caused not only by restricted or unbalanced diet or voluntary prolonged abstinence but by pathologic processes or serious dysfunction of the gastro-intestinal tract gravely interfering with proper nutrition goes back almost a decade. In 1931 Eusterman and O'Leary¹⁰ reported observations concerning thirteen cases of pellagra which developed during the course of disease or dysfunction of the digestive tract. Several similar striking cases of deficiency of vitamin G have been observed since then. We have also seen two cases of pronounced nutritional edema with the usual marked decrease in the value for total serum proteins and with disturbed mineral metabolism, following operations for benign lesions of the upper part of the digestive tract, in which the sequelae were those of obstruction of high grade. Fortunately, such instances are extremely rare when operation is carried out by competent experienced surgeons.

The night blindness in the case here reported also rather convincingly developed as the result of a post-operative complication, in which the clinical feature of deficiency of vitamin A was prominent. In our opinion this is the first example of a highly probable nutritional night blindness on record in the clinic. It is not unlikely that more meticulous study would have revealed other deficiency disorders in the thirteen cases of pellagra previously reported for such disorders are usually multiple in man but the clinical evidence for this was not obvious. Students of nutrition and clinicians have emphasized in recent writings the importance of excluding organic disease of the digestive tract when confronted with a deficiency disorder. Other conditions formerly not looked on as deficiency diseases such as pernicious anemia, sprue, gastric dyspepsia of Schmidt and idiopathic steatorrhea are also apparently dependent on a disturbance of gastro-intestinal function resulting in deficient production, absorption or utilization of one or more essential factors. Also evidence has been advanced recently by Minot¹¹ and Strauss¹² and their associates indicating that the polyneuritis of pregnancy and probably alcoholic polyneuritis are deficiency disorders.

It is imperative carefully to investigate the diet of all patients with ill defined complaints, dental defects, lowered resistance to infection, lack of physical well being, inhibition of bodily development and the like. States of partial deficiency may be very common, and the lack of adequate intake of calcium is particularly striking.

SUMMARY

Report of a case of highly probable nutritional night blindness is made because of the rarity of reports of such cases occurring in the United States. The relationship of this symptom to deficiency of vitamin A and the retinal pigment visual purple are considered. It is worthy of emphasis that states of nutritional deficiency may arise as in this case not as a result of inadequate intake of vitamins or other foodstuff but as a result of gastro-intestinal or other disturbances interfering with either the normal digestion and assimilation of foodstuffs or their metabolic activity.

Clinical Notes, Suggestions and New Instruments

AN AID TO SPECULAR EXAMINATION

BEATRICE E. TUCKER, M.D., CHICAGO

At the Chicago Maternity Center we have been using a simple device, contrived by Dr. DeLee, to improve vaginal specular examinations, as shown in the illustration. A $2\frac{1}{2}$ inch rubber sleeve, used in making cigaret drains, is slipped over the regular duckbill speculum. When the blades are opened a rubber side-wall is formed, which keeps the vagina from pouching into the field. This device is particularly useful in multiparas and pregnant women with relaxed and redundant

Device to improve specular examinations consisting of bivalve vaginal speculum with a section of Penrose drain used as a sleeve

vaginal walls. It also obtains good exposure for colposcopic examination and forms a protection to the tissues when the cervix is cauterized.

CONGENITAL PROCTOLOGIC DEFECTS IN TWINS

C. C. MECHLING, M.D., PITTSBURGH

The occurrence of identical congenital defects in identical twins is a rarity. An instance of this has been observed in male twins 23 years of age.

The small skin-lined congenital sinus located under the skin over the lower sacrum is usually not observed until inflammation has occurred and it is probable that many such sinuses exist without ever being discovered. When inflammation, with pus formation sets in it will require incision with drainage and a later excision of the cutaneous-lined sinus to effect a complete cure.

A vigorous healthy twin, a man aged 23, was seen with an abscess apparently located in the subcutaneous tissue over the lower sacrum. It was incised and drained and, six weeks later, the acute cellulitis having subsided, was excised *en bloc*. It was positively identified by the pathologist as being of the congenital type—a pilonidal fistula. One year later the second twin presented himself with a similar abscess. It was treated by the same method.

In a series of 7,500 private proctologic cases seen in a period covering twenty years I have seen seventy-two patients 0.96 per cent with pilonidal disease—either the acute abscess or the chronic fistula. This is my first observation of this condition in twins.

THE OUTBREAK OF AMEBIASIS IN CHICAGO DURING 1933

SEQUENCE OF EVENTS

HERMAN N. BUNDESEN, M.D.
President, Board of Health

FRED O. TONNEY, M.D.
Director, Technical Service and Research

AND

I. D. RAWLINGS, M.D.
Chief, Bureau of Communicable Diseases
CHICAGO

There have been so many conflicting statements regarding the recent outbreak of amebiasis in Chicago that we take this occasion to recite briefly the sequence of events as they occurred.

On August 16, two cases of amebic dysentery in two different hospitals of the city were reported to the Board of Health. An immediate investigation was ordered. It was found that both patients had eaten in a certain hotel, and further inquiry revealed some diarrheal cases in this hostelry. Two additional cases among the guests were also found. On the basis of this evidence, a temporary laboratory was set up on the premises on August 17, and stools from all the food handlers were collected and examined under supervision of trained technicians who were experienced in the diagnosis of amebiasis.

Out of 364 food handlers examined in this first survey up to September 1, 15 clinical cases and 11 carriers of *Endamoeba histolytica* were found. In addition, there were five other clinical cases among the non-food handling personnel.

The infected food handlers were excluded from the kitchens and stringent sanitary regulations were put into effect with unusual measures of sanitary supervision designed to check further spread of the disease to the patrons of the hotel. With these stringent control measures in effect, and with the carriers removed, no further apprehension was felt about additional cases by Drs. Tonney and Rawlings, who were in charge of the situation.

During the month of September, the situation was watched for possible developments. It was believed at that time that this was a strictly food-borne outbreak. It is to be borne in mind that no previous food handling outbreaks of amebiasis of serious proportions had ever been reported. No new cases were reported among the guests of the hotel which were not attributable to earlier infection, nor were any more than the usual number of clinical cases reported in the city at large. In fact those reported from sources other than the laboratory survey cited were less than the normal expectancy.

Nevertheless, in order to bring the matter to the attention of health officers, special arrangements were made to report the first laboratory survey of this hotel to the annual convention of the American Public Health Association in Indianapolis. The paper was presented on Oct. 9, 1933, by Tonney, Hoeft and Spector. It was given some publicity in the local press of Indianapolis on October 9, and a news item was sent out by radio over the NBC network from the "Radio

Forum" which was part of the official program of the Convention. News releases were also issued from the Association headquarters, but these were not generally accepted by the press.

Later on in the day, Dr. Tonney was advised by a citizen of Indianapolis that there were in his family two cases of amebic dysentery which had developed after a recent visit to Chicago. On inquiry, it was learned that these persons had stopped in the hotel referred to. Further inquiry among physicians in Indianapolis brought to light a total number of eight cases, apparently originating from the same focus in Chicago.

These facts were reported to the President of the Board of Health on October 19, immediately after returning from the convention. Meanwhile, some additional clinical cases were appearing in the nonfood handling personnel of the hotel which as yet had not been examined by the laboratories. These together with the discovery of two new cases in the guests, brought the realization that the situation must be more serious than had been recognized. One of the two guests was a resident of long standing in the hotel but the other, taken ill in October, had registered only a short time before, and had not been in the hotel at all during the summer.

It was therefore decided to extend the examinations to include the nonfood handling personnel and also to reexamine the food handlers, provided means could be found to finance the work. These costs were underwritten by the hotels served.

Accordingly, the local universities were asked to provide competent technicians, and after preliminary arrangements were made for financing, organizing personnel and equipping the laboratory, the second survey of the hotel personnel began on October 27. This investigation revealed fifty-three more food handlers infected and sixty-five nonfood handlers up to November 24.

Although amebic dysentery is a reportable disease by law, no unusual number of cases had been reported in Chicago up to October 27.

Because of the illnesses reported at Indianapolis however, it was decided to attempt to find out if any cases were occurring outside of Chicago. For this purpose, sixteen thousand questionnaires were sent to guests registered at the hotel during the three months' period June to August. Permanent residents of the hotel and persons living in Chicago but registered at the hotel under unidentifiable names were not included in this survey.

As the questionnaires were returned, those persons reporting any intestinal ailment were called by long distance telephone or were sent a telegram urging immediate medical care. It was requested that a return telegram be sent at once (collect), giving the name of the attending physician. As these came in, more long distance telephone calls went out to the doctors, suggesting that they be on the lookout for amebiasis in the patients.

By the evening of November 8 about thirty-five replies were received indicating diarrheal disturbances and it was then decided that the situation was sufficiently serious to justify issuing a general warning to the press. On November 9, therefore, a news release was sent to the press by the Board of Health and the circumstances were reported to the Surgeon-General by long distance telephone with the request that consider-

ing the apparent interstate importance of the outbreak, a representative of the federal government be sent to Chicago to confer.

On November 10, another statement prepared in cooperation with a representative of the United States Public Health Service was released. On November 14, a special broadcast was made over the NBC network, from coast to coast and in Canada with the appeal to those suffering from intestinal disorders to see their doctors and to physicians to be on the lookout for amebic dysentery.

The original article presented in Indianapolis was published, together with another report on the later developments in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* on November 18, namely, "The Health Hazard of Amebic Dysentery. Report of an Outbreak" by Dr. Herman N. Bundesen, Dr. I. D. Rawlings and Dr. William I. Fishbein, and "The Threat of Amebiasis in the Food Handler" by Dr. F. O. Tonney, Gerald L. Hoeft and Dr. Bertha Kaplan Spector.

When the second survey of physical examinations of employees was completed, about the middle of November, it revealed that there were carriers in the hotel who had not been found infested on the first examination. It began to become apparent that control over food was not checking the infection. At the same time the returns of questionnaires were indicating the true size of the outbreak. It was therefore decided that although water had not been commonly implicated in epidemics of amebiasis, the possibility of water contamination should be investigated.

Therefore, on November 22 a detailed investigation of the water and sewage piping of the hotel was begun. Conditions were discovered indicating that a careful check of the entire system was desirable. Verbal notices were given as rapidly as potential hazards were discovered. On November 27, a general notice was sent to the hotel directing the correction of conditions which might possibly permit contamination of the water. Because of the complexity of the system, this notice was sent before the survey had been completed in order to get corrective measures started without delay.

While investigating the physical plant of one of the hotels on January 3 the chief engineer of the hotel revealed that on July 2 two sewer pipes had broken under the ice storage room, permitting sewage to flood areas where food and ice were stored prepared and handled, and also where 345 food handlers worked, many of whom ate their meals in the basement in the quarters which were flooded.

Following this lead it was also found that water and sewage had penetrated into the ice-handling area of the other hotel during a heavy rain on June 29. Subsequently, it was also learned that there had existed in one hotel connections between water and waste pipes through which contamination of the water supply of portions of both hotels might have occurred. The location and character of these cross-connections were such as to make them serious potential hazards.

Since that time the Health Survey Laboratory in this hotel has been continuously maintained. Five surveys of food handlers and two surveys of nonfood handlers have been completed. A sixth survey is under way. To date 165 food handlers and 141 nonfood handlers out of approximately 1,100 employees have been found infected in this institution.

Up to January 24, 721 clinical cases of amebic dysentery in 206 cities, including Chicago have been reported as apparently originating from this source. In addition, there have been 1,049 carriers of *E. histolytica* brought to light in Chicago by our investigations. There have been fourteen deaths in this city from the disease.

A general laboratory survey of all the principal hotels of the city, as well as the larger restaurants, has also been made by the laboratories of the Board of Health.

No condition paralleling that of the two original foci has been found in any other Chicago hotel. In an industrial plant in Chicago, employing approximately 375 workers, a cross-connection permitting raw river water to contaminate the water supply of the plant was made in December. An outbreak of diarrhea in this plant followed shortly after. Investigation by the Board of Health revealed 7 cases of amebic dysentery, 71 carriers of *E. histolytica* and 3 cases of typhoid fever following this contamination by raw river water.

Realizing the peculiar circumstances concerned in this outbreak and the widespread interest of public health officers, the Board of Health is endeavoring to prepare a complete and detailed report of all phases of the epidemic which will, when ready, be made generally available.

AMEBIASIS OUTBREAK IN CHICAGO

REPORT OF A SPECIAL COMMITTEE

NOTE.—Following is the report of a committee assembled by the President of the Board of Health of Chicago, Dr. Herman N. Bundesen, to consider an outbreak of amebic dysentery in that city during the summer and fall of 1933. The members of the Committee were selected by a preliminary subcommittee consisting of Drs. Herman N. Bundesen, Morris Fishbein, Ludwig Ecktoen, F. W. O'Connor and Milton M. Portis. The Committee met in Chicago from January 22 to January 26 inclusive. The members of the Committee heard reports from the heads of various bureaus involved in a study of the outbreak and also inspected at first hand the premises concerned.—EDITOR

The Committee, after careful investigation of the clinical histories and laboratory evidence of the epidemic of dysentery which originated in Chicago during the summer and fall of 1933, is convinced that the epidemic was one of amebic dysentery, and not of bacillary dysentery.

Until 1933 amebic dysentery had not figured largely in the morbidity and mortality reports in Chicago or indeed in any city in the United States. The outbreak in 1933 embraced about 800 reported cases, most of which became apparent in cities other than Chicago. A large majority of these were traced to two hotels as probable sources of infection. Some of the cases were not so traceable.

In considering this outbreak the unprecedented nature of the occurrence must be borne in mind. Until this time, amebic dysentery had not been known to occur as an epidemic disease in a civil population.

Members of the Committee have examined the original records and in addition clinical cases of amebic dysentery and carriers originating in Chicago at the hotels concerned in the cities outside of Chicago and in the Municipal Contagious Disease Hospital in Chicago. They have examined the laboratories established to examine carriers and cases by the Chicago Board of Health. They have examined the technic

involved and the prepared specimens as well as the cultures of *Endamoeba histolytica* obtained. They have examined the physical equipment of the hotels involved as related to food handling, plumbing and sewage.

The Committee presents herewith its observations the significance of the observations and its recommendations for the prevention of possible epidemics of amebic dysentery in the future in the light of these studies.

LABORATORY DATA

The methods used for the determination and identification of *E. histolytica* were the direct smear method the staining of smears with iodine and approved cultural methods as well as fixed and stained slides. In addition to this, necropsy material was also obtained and studied. The Committee is convinced that these methods were adequately and properly carried out by a well qualified personnel and resulted in the identification of *E. histolytica* in all of the so diagnosed cases and carriers observed.

SANITARY ENGINEERING SURVEY

In undertaking an investigation of the sanitary engineering features related to the outbreak of amebic dysentery in Chicago, the physical or structural factors of the sanitary equipment of the two hotels chiefly concerned were surveyed. An initial inspection, made on Nov. 22, 1933, disclosed sufficient causes for further detailed review, and such examination has been carried on to this time. Sufficient preliminary evidence on a number of major aspects has already been accumulated to warrant presentation.

Both the hotels have their source of water supply from the public water mains of the city of Chicago. Owing to the heights of the buildings however, supplementary pumpage is necessary.

Water is taken from the city mains in Hotel C and pumped to two sets of tanks, one of which is on the roof of the main Hotel C building and the other on the roof of the annex of Hotel C. The pumps in the Hotel C basement in addition, deliver water to the upper stories of Hotel A by way of tanks beneath the roof of Hotel A. Hotel A, at least in its major part, has therefore, a common source of supply with Hotel C. The basements and lower stories of both hotels probably obtain the major portions of their supply directly from the city of Chicago water mains.

From the field investigations so far made, three important groups of structural sanitary hazards were found in both hotels. In order of increasing importance, they are tentatively listed as:

- 1 Old and generally defective water and sewerage piping layouts, potentially at least permitting back siphonage of a number of fixtures such as bath tubs and flush toilets, into water lines.

- 2 Chance breaks in sanitary sewers or heavy overflows of mixed sanitary sewage and storm water drainage in and outside of the basements.

- 3 Cross-connections of serious character between water and sewer lines or between water lines carrying potable water and water potentially subject to contamination.

With reference to class 1 (old and generally defective water and sewerage piping layouts, potentially at least permitting back siphonage of a number of fixtures such as bath tubs and flush toilets, into water lines) the water and sewer systems in both hotels are typical of layouts in the older buildings in Chicago and in other American cities. They are a potential source of danger, but do not, except under special circumstances,

such as continuous overloading by capacity use of the facilities of the hotel, produce extensive pollution. Their hazard is of a limited, rather than of an explosive, general nature.

In class 2 (chance breaks in sanitary sewers or heavy overflows of mixed sanitary sewage and storm water drainage in and outside of the basements), several events occurred during 1933 which may have some significance in determining the cause of the epidemic. On June 29, 1933, an unusually heavy rainfall (2.81 inches in twenty-four hours) occurred in the city of Chicago. It flooded the combined sanitary and storm water sewers of the city including those in the streets in the vicinity of these hotels. The flood waters penetrated the basement of Hotel A through an alley manhole and reached the ice storage house, according to the statement of employees in the basement. This flooding extended over some hours.

The rain of June 29 was followed by a second unusual rainfall on July 2 (1.63 inches in twenty-four hours). On this occasion, according to statements made by hotel employees in January, 1934, early in the morning of July 2, 1933 (approximately between 2 and 3 a. m.) two sewers from Hotel C, discharging into the public sewer, broke. Sewage flowed back into the basement of Hotel C directly into the ice storage house. It is stated that a hole was torn in the wall and floor of the ice storage house approximately 8 to 10 feet in diameter, the sewage rose to the ceiling of the ice storage house until its pressure forced one of the closed doors of the ice house open. The opening permitted the sewage to flow over a considerable portion of the basement of Hotel C. This sewage covered much of the entire food handling establishment of the hotel to a depth of 3 to 6 inches according to statements by employees.

So far as the class 3 hazards (cross-connection of serious character between water and sewer lines or between water lines carrying potable water and water potentially subject to contamination) are concerned, a number of cross-connections were found and these have since been eliminated. Such cross-connections between sewers and water lines are significant as a public health hazard since they may permit sewage to flow into water lines.

EPIDEMIOLOGY

The results of the questionnaires sent out by the Chicago Board of Health to the guests and patrons of the two hotels involved as well as to those of several other hotels in which there was no evidence that cases originated, clearly demonstrates that these two hotels were the source of most of the cases so far traced.

An examination of the data resulting from a study of the incidence of *E. histolytica* in the stools of employees in these two hotels, as well as in many other hotels and restaurants in the city shows that 3.9 per cent of employees in hotels and restaurants in general in Chicago are carriers of *E. histolytica* or suffer from amebic dysentery. This incidence is about equal to that of the population of the United States in general.

In Hotel C, on the other hand, at the time of the first survey (August 17 to September 1) 7.1 per cent of the food handlers were found to be infected. As the result of additional surveys of the food handlers in this hotel, as well as in hotel A, it became evident that at times more than 18 per cent of these employees were infected.

It was evident from the first survey of food handlers of Hotel C that they were a possible source of infection

for guests and patrons of the hotel, and control measures were instituted, including the removal of carriers from employment, which were calculated, in the light of previous knowledge, to control the epidemic. In spite of these measures, cases continued to develop among employees of the hotel. The percentage of those infected among non-food handlers was found to be approximately the same as among food handlers.

Because of these facts an investigation of the sanitary engineering conditions of the hotels was undertaken, and the conditions as reported were found.

These observations offer presumptive evidence that structural defects, either permanently or intermittently operative in one or both of these hotels were associated with the development of the unusual incidence of amebiasis. Although similar defective structural arrangements no doubt exist in Chicago, as well as in other cities of the United States, only special and fortuitous circumstances may bring them into play to cause a severe epidemic.

This conclusion is further strengthened by the knowledge that, experimentally, extremely large doses of *E. histolytica* have to be administered to both man and animals to produce infections comparable to those observed in this epidemic, in which the incubation period was short, the lesions were severe and the exposures were frequently minimal. These features were out of proportion to what would have been expected if smaller doses had been obtained by contamination from fingers of food handlers exclusively.

GENERAL RECOMMENDATIONS

1 Cases of amebiasis (including amebic dysentery) should be promptly reported *as such* to the lawfully constituted health authorities of the community.

2 Carriers not engaged in food handling should be treated but not required to vacate their occupations.

3 The feces of untreated and insufficiently treated carriers and convalescents and sometimes those of active cases contain the infective (cysts) form of the parasite. Therefore, the stools of such persons should be disposed of according to local sanitary regulations. Those infected should be informed of the manner of transmission of the disease treated and cautioned to

(1) Wash their hands thoroughly after using the toilet.
(2) Avoid depositing their feces where they can be exposed to flies and other insects or where they can contaminate food, water or articles handled by other persons.

(3) Avoid preparing and handling food to be eaten by other persons until considered incapable of spreading the disease.

Laboratory examination of the feces of food handlers should be required if circumstances point to a particular individual or group of individuals as a possible source of infection. The general examination of all food handlers for *E. histolytica* is considered impractical.

4 A patient or carrier should not be allowed to become a food handler unless after an interval of at least seven days since the completion of his treatment three negative examinations of feces are made at intervals of at least one day. Thereafter to continue as a food handler, a person should have at least four negative stool examinations at intervals of one month.

RECOMMENDATIONS CONCERNING SANITARY ENGINEERING

1 Sanitary engineers have for years recommended, and the laws of practically every state and municipality

provide, that water and sewer installations should be so arranged as to prevent absolutely contamination of water supplies for domestic use by water of nonpotable quality. The Committee recommends that attention be called again to this extraordinary hazard and the necessity of rigid enforcement of these regulations.

2 No physical connection should be permitted between water supply systems that are safe for domestic use and those that are unsafe for domestic use. There should be no provision for a connection or arrangement by which unsafe water or sewage may be discharged or drawn into a safe water supply system.

3 An exhaustive and searching study of the whole water and sewage systems of hotels with antiquated plumbing should be made and any defects immediately corrected. This work should be done only by competent sanitary engineers.

4 The present conditions under which, during periods of flood, flood waters from the street can reach and cause an overflow of sewage in the basements of any hotels should be thoroughly investigated by officials having jurisdiction, and methods adopted to prevent such an occurrence. Unless the antiquated plumbing and conditions of food handling found in Hotels C and A are remedied, there seems to be no warrant that a recurrence of the outbreak here considered may not develop under similar conditions.

CONCLUSIONS

1 It is believed that this outbreak might not have been recognized and traced to Chicago without the action taken by the Chicago health authorities. The direct contacts established by the president of the Board of Health with guests previously registered in the hotels concerned as soon as he had learned of cases in other cities traceable to Chicago served to bring to light the majority of the more than 700 cases in some 206 cities thus far reported.

2 The measures taken by the public health authorities of Chicago when there was sufficient evidence to warrant the belief that the population of the city and its visitors were faced with the menace of amebic dysentery were those generally recommended and generally considered sufficient in the light of the best scientific advice and in conformity with the best public health practice. Exclusion of carriers among food handlers and sanitary precautions with respect to all food handlers had apparently been applied successfully in an outbreak in Chicago in 1926-1927.

3 Evidence supports the conclusion that cases of amebiasis are frequently diagnosed incorrectly and that as a result specific methods of treatment are not administered sufficiently early and with sufficient intensity to secure successful outcome. Inadequate treatment of both carriers and those suffering from amebic dysentery accounts for many recurrences. Those under treatment should be watched carefully for clinical symptoms of recurrence. Laboratory evidence should be sought immediately to establish the nature of the recurrence. Courses of treatment may need to be repeated sometimes substituting other well recognized drugs for those first employed.

4 The researches carried on by the Chicago Board of Health have already thrown further light on the epidemiology and mode of transmission of amebic dysentery, a disease about which our knowledge is defective in many respects. Further studies are needed

before we can be in possession of all the facts necessary to enable public health authorities to combat successfully the spread of this disease.

LABORATORY EXAMINATION AND DIAGNOSIS

The conclusive diagnosis of amebiasis rests primarily on laboratory observation, and depends on the demonstration of *E. histolytica* in the stools, discharges or tissues of the suspected person. A negative report, however, does not necessarily mean absence of infection.

Stool Examinations—As a rule, only the motile forms (trophozoites) of *E. histolytica* are found in liquid or semi-liquid stools, while cysts are found usually in formed stools. However, flakes of blood or mucus on formed stools frequently contain motile forms.

The best results will be obtained by examination of very freshly passed specimens and whenever possible the patient should pass his stool at the laboratory where he is to be examined. So far as is possible, the entire stool should be available for examination. If the stool is fluid or contains blood or mucus, it is imperative for the identity of motile forms that it be examined before it has had time to reach room temperature.

While it is true that satisfactory results may be obtained by the examination of formed stools which are not perfectly fresh, it is nevertheless desirable to have them as fresh as possible, delayed examinations are usually unsatisfactory.

To obtain motile forms from persons passing formed stools, a suitable dose of magnesium sulphate should be administered, and the first liquid stool examined.

Stools are unsatisfactory for examination when they follow the administration of oil barium bismuth or oily suppositories, and the container used for collecting the specimen should be clean and dry. Urine should not be passed into the container.

If the condition of the patient prevents the direct collection of the specimen in the laboratory arrangements should be made to bring the specimen to the laboratory at once, and in any event if motile forms are to be searched for, the specimen should be kept at body temperature.

A very serviceable container for formed specimens is the standard seal-tight, half-pint paper carton.

Technic of Stool Examination—1 *Unstained Smear Preparations*. If flakes of blood or mucus are present in the stool they should be selected for examination. If the stool is liquid any portion may be used after stirring. If the stool is formed samples should be taken from different portions, including the outside and the interior. A useful instrument for making smears is a standard wooden applicator.

Upon a clean glass slide place a capillary drop of physiologic solution of sodium chloride (0.85 per cent). Thoroughly mix a portion of the stool in this drop so that when a 22 by 22 mm cover glass is dropped upon it one can readily read newspaper print through the emulsion. Under no conditions should fewer than two cover glass preparations be examined. The preparation should then be examined under the microscope with a low power (ocular 10 × objective, 16 mm) preferably with the aid of a mechanical stage so that in some regular manner all of the area is covered. Suspicious objects should then be critically examined under high power (4 mm objective). If necessary, oil immersion examination may also be used. In addition to this examination, the stool should be examined in the following manner:

2 *Iodine Smear Preparations*. The purpose of the iodine is to demonstrate the number and characteristics of the nuclei within the cysts and also to show the characteristics of glycogen material in the protoplasm of the cysts. Because the iodine frequently is slow in penetrating the cysts a short interval of time should elapse before examination of this preparation.

Place on a clean glass slide a drop of compound solution of iodine and emulsify the same quantity of stool in it as in the saline preparation. After placing a cover glass on it, examine in the same way as described.

Some workers prefer to use a 1:1,000 solution of aqueous eosin yellowish, dissolved in saline solution and to add this solution to the iodine, instead of using compound solution of iodine alone. Some experience will be necessary to determine the exact amount to be added, but equal parts are generally satisfactory.

3 Concentration Methods. In examining formed stools concentration methods are frequently useful. The following procedure is recommended.

A portion of stool equal to the size of a pea is thoroughly emulsified in saline solution in a centrifuge tube the tube filled with saline, at moderate speed for one minute centrifuged and the sediment examined by the methods outlined in 1 and 2. It may be necessary, if coarse particles are present in the stool to strain it through two layers of cheesecloth before centrifugation after it has been diluted with saline solution.

4 Staining Methods. Many fixing and staining methods have been proposed which, in the hands of experienced workers, have been found to be extremely useful in the identification of doubtful specimens. However, it is not essential to use such methods for routine diagnosis.

5 Culture Methods. Various satisfactory culture methods have been reported and can be found in original papers or in recently published text-books on parasitology. It must be apparent that a well appointed bacteriologic laboratory is necessary to prepare and use suitable mediums, therefore the use of culture methods is limited. It must be recognized that if cultures are used in addition to smear methods, occasional additional positive cases will be discovered that were negative by the smear method. On the other hand the experience, labor, and skill necessary for the use of cultural methods will make them impractical for ordinary routine diagnosis.

Discharges Other Than Fecal Material.—One may examine these by the same general methods described under smear examination and cultural methods, making such modifications as will be obvious to the examiner. Such discharges are likely to contain only motile forms.

Complement Fixation.—This method is intricate and the antigen is so difficult to prepare that it is not considered justifiable to recommend it as a routine procedure at present.

Examination of Tissues.—Any tissue suspected of containing *E. histolytica* should be fixed in either Schaudinn's or Zenker's solution. After sectioning the tissue some sections should be stained with iron-haematoxylin, as this stain brings out the nuclear structure of the ameba.

Number of Stool Examinations.—The number of examinations will obviously have to depend upon the circumstances under which the worker is conducting his tests, the methods employed and the skill of the observer. In examining formed stools, from one third to one half of all persons harboring *E. histolytica* should be detected on the first examination, approximately three fourths of the total number of cases on two examinations and six examinations should detect practically all cases. These examinations should be spaced at least twenty-four hours apart.

If fluid stools are examined, approximately three fourths of the cases should be detected on the first examination, and in three specimens one should detect practically all of the cases.

The existence of at least five different species of amebae living in the human intestine makes it most essential that one should differentiate the pathogenic *E. histolytica* from the four nonpathogenic species. Standard texts dealing with the intestinal protozoa contain descriptions of these differential features.

The diagnosis of amebiasis and the differentiation of *E. histolytica* from other amebae should be attempted only by those qualified by special training and experience. Unfortunately at the present time, comparatively few clinical pathologists and technicians have received adequate training in this field. No one should be considered satisfactorily qualified unless he has received adequate training under a qualified instructor.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

OYE FOOT SPRAY NOT ACCEPTABLE

This unit consists of a container resembling a wash boiler arranged so that the patient's feet may be confined within it. Pipes with a series of small holes (nozzles) are arranged to spray either hot or cold water, or both, on the feet. If the unit is used in the home, it is recommended to be placed in the bath tub and the hose connections fastened to the faucets of the tub.

The Oye Foot Spray was submitted by Ida St. John Oye 901 Washington Avenue, Brooklyn. Several claims are made for it:

- 1 It perfects the condition of feet of men and women
 - 2 It gives a needle spray
 - 3 It gives hot and cold quickly interchangeable
 - 4 Pressure from the spray gives percussion on nerves and ligaments
 - 5 Treatment for sprained ankle
- It is recommended for use in the home by physicians, clinics, chiropractors, beauty parlors and barber shops.

The unit was investigated. The Council declared that it did not find any special advantage in the apparatus over that obtained by the use of an ordinary rubber hose and nozzle. It also declared that simpler, more convenient and less expensive methods were available for treating a sprained ankle.

The Council found the Oye Foot Spray ineligible for inclusion in the Council's list of accepted devices.

K-M INFRA RED RAY LAMP, TABLE MODEL NO 630, NOT ACCEPTABLE

The Infra Red Ray Lamp manufactured by the Knapp-Monarch Company, Belleville, Ill., has been given consideration by the Council on Physical Therapy. The Table Model type examined resembles a reading lamp in outward appearance, the difference being that an electrical heating element takes the place of an electric bulb. The element draws about 300 watts on a 110 volt circuit on either alternating or direct current. The Council finds little difference, if any, in therapeutic effect between this infra-red ray lamp and an ordinary bathroom heater.

The blue covered booklet describing the lamp contains many objectionable, unwarranted or misleading statements. Among others, the following paragraphs may be cited as misleading:

Infra red rays penetrate under the surface of the skin to a depth of four to six inches and form heat units which cause an excess accumulation of blood.

Catarrhs of the stomach and intestines tend to disappear, the digestive secretions resume their normal functioning and the liver, adrenals, lymphatic glands and other poison-destroying organs are again effective.

Infra Red rays hasten the disappearance of fat by the oxidation of excess tissues. They are of great value in the treatment of organic or functional heart disease because from one third to one half of the entire volume of blood can be stored in the capillary system—thereby relieving the heart of its hardest work.

Other misleading as well as absurd statements follow:

DOCTOR SUN—The World's Greatest Physician

The smoke and dust of cities, the atmospheric density of low altitudes and the general uncertainty of sunshine all combine to make it almost impossible for the average person to get the desired benefits from sunbaths regardless of the individual desire or need.

But in recent years it has been found possible to build lamps which duplicate the different rays of the sun—which have been demonstrated through actual tests and experience to produce virtually the same beneficial results as the sun itself.

In this booklet (pages 4, 5, 6, 7 and 8) there is a list of thirty-one so-called "Common Ills" for which there are given suggested methods of treatment. Among other misleading indications for the therapeutic use of infra-red rays, the firm lists the following diseases: angina pectoris, asthma, biliousness, heart disease, itch and delayed menstruation.

The Council is not in possession of critical evidence to support these unwarranted suggested indications for the therapy.

peutic employment of infra red radiations. Promotional advertising matter of this kind is bound to be misleading and in effect constitutes an appeal to the public with arguments that are unscientific and may harmfully promote a feeling of false security on the part of the public.

The Council on Physical Therapy declares the K-M Infra Red Ray Lamp Table Model No. 630 unacceptable for inclusion in the Council's list of accepted devices because the firm in its advertising matter violates the rules of the Council.

Council on Pharmacy and Chemistry

The Council on Pharmacy and Chemistry of the American Medical Association records with profound regret the sudden death of one of its members.

ALFRED FABIAN HESS

on December 5, 1933, in New York City at the age of 58 years.

After graduating from Harvard University with the degree of B.A. in 1897, he attended the College of Physicians and Surgeons in New York City, from which he received the degree of M.D. in 1901. Subsequently he studied abroad at various continental universities. Dr. Hess early devoted his attention to the practice and problems of pediatrics to which he was destined to make notable contributions. He pursued his ideals without cessation until the day of his death.

The scientific investigations of Dr. Hess included many fields of the extensive domain of child welfare and the diseases of children. He had an unusually wide familiarity with the literature of the subject, he was personally acquainted with many distinguished colleagues throughout the world of scientific medicine, he managed in a broad way to acquire an understanding of the ever-changing technique of scientific research, he always had a virile approach to its unsolved mysteries.

Some of Dr. Hess's achievements deserve special mention even in a brief reference to his life work. His book on "Scurvy, Past and Present," published in 1920 promptly won distinction for its author. It was the first really comprehensive monograph on this important disease published since that of Lind more than a century ago. Embodying much of Hess's own thorough investigations, his volume brought together in a masterly way and an interesting style items of great value to the clinician, the hygienist, the biologic chemist and the medical historian. Of comparable importance is the newer volume by Hess on "Rickets Including Osteomalacia and Tetany," published in 1929. In this the admitted master of the subject has brought together the results of his vast experience and ripe judgment.

Dr. Hess has been among the pioneers in the study of the vitamins. His most significant contribution was his discovery of the effects of ultraviolet rays in developing antirachitic potency in many foods. Through these studies and his collaboration with European scientists, the relation of ergosterol to vitamin D ultimately became established.

In 1927 Dr. Hess received from the Academy of Natural Science in Philadelphia the John Scott Medal and \$1000 for devising 'a method of producing a vitamin factor in food by ultraviolet light.' Other academic honors have come to him. His advice was widely sought and freely given without thought of reward. He contributed liberally of his time and material things to philanthropic and scientific undertakings. At the time of his death Dr. Hess was president of the Harvey Society.

Dr. Hess became a member of the Council in 1932 and served energetically and enthusiastically until his death. He had previously been a valued consultant of the Council. His colleagues recall Dr. Hess's quiet deliberate manner, his forceful advice and his judicial attitude. Like many others among his wide circle of acquaintances they retain the memory of his sincerity, his wisdom, his personal loyalties and his devotion to the best ideals of his generation.

Committee on Foods

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTIG, Secretary

MCCORMICK'S PREPARED MUSTARD

Manufacturer—McCormick and Company, Inc., Baltimore

Description—Prepared mustard manufactured from distilled vinegar, English and American yellow and brown mustard seeds, salt, sugar and spices.

Manufacture—The mustard seed is aged to develop flavor, cleaned, crushed, and mixed with spices, distilled vinegar, salt and sugar. The mix is ground and automatically bottled.

Analysis (submitted by manufacturer) —

	per cent	Fat, salt and sugar free solids basis per cent
Total solids	18.4	
Total ash	4.6	
Acid insoluble ash	0.1	1.1
Sodium chloride	4.1	
Nonvolatile ether extract	3.2	
Volatile oil	0.04	
Nitrogen	0.65	7.2
Protein (N \times 6.25)	4.0	44.2
Sucrose	2.0	
Crude fiber	0.9	9.9
Copper reducing substances by direct inversion	1.3	14.4
Titrateable acidity as acetic acid	2.4	

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard.

LONG'S OX-HEART BRAND PEANUT BUTTER

Manufacturer—Oswego Candy Works, Inc., Oswego, N. Y.

Description—Peanut butter seasoned with salt.

Manufacture—Selected peanuts are roasted, run through peanut blanchers to remove the embryo and red skin, again inspected, ground, salted to taste and sealed in jars.

Analysis (submitted by manufacturer) —

	per cent
Moisture	2.8
Ash	2.8
Fat (ether extract)	50.9
Protein (N \times 6.25)	28.8
Crude fiber	2.3
Carbohydrates other than crude fiber (by difference)	12.4

Calories—62 per gram, 176 per ounce.

LIGHT CRUST FLOUR (BLEACHED)

Manufacturer—Burrus Mill & Elevator Company, Fort Worth, Texas.

Description—A patent flour milled from hard and soft wheat, bleached.

Manufacture—Selected hard and soft wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, page 2210. Chosen flour streams are blended, and bleached with nitrogen trichloride (one seventh ounce per barrel) and benzoyl peroxide and calcium phosphate (three-sevenths ounce per barrel).

SHEFFIELD "SEAELECT" BRAND UNSWEETENED EVAPORATED MILK

Manufacturer—Sheffield Condensed Milk Co., Inc., New York.

Description—An unsweetened, sterilized evaporated milk. The procedure of evaporation and canning is essentially the same as for the usual evaporated milk. (THE JOURNAL, April 16, 1932, p. 1367).

SATURDAY, FEBRUARY 3, 1934

SUBCLINICAL SCURVY

The rapidly growing information with respect to the nature of the so-called deficiency diseases includes evidence that there are many instances of latent avitaminosis or subacute disorder not commonly recognized. Obviously persons who give no conspicuous evidence of deficiency maladies may nevertheless be victims of the effects of less than optimal or of minimal necessary intake of essential dietary components. The harm done may be particularly insidious through not being recognized in the absence of the gross manifestation of unmistakable disease. Bacterial infections rarely present such subtle symptoms for any prolonged period because the invasion of the harmful offender tends to become more and more threatening as the days go by. The symptoms soon develop into characteristic phenomena of specific maladies. Latent avitaminosis is something far more subtle. It more readily defies recognition except through painstaking special modes of clinical investigation. At the present time accelerated efforts are being directed to the earlier diagnosis of deficiencies, notably in relation to some of the vitamins. This is particularly true of vitamin C, the essential substance that protects against scurvy.

In his classic treatise on this disease, A. F. Hess¹ pointed out long ago that it may develop and progress in various ways. It may remain latent for a long period and be cured by some accidental change of diet, or, as more frequently occurs, it runs a moderately acute course and is promptly cured by means of antiscorbutics. Hess remarked that the syndrome which the medical student is taught to carry away to guide him in his everyday practice is the acute, florid type and presents a striking picture but must not be regarded as the common form of the disorder. If infantile scurvy is to be diagnosed early and if its more subtle manifestations are not to be overlooked, the classic textbook description must be augmented by portrayals of types of the disorder that are less crude and more diffi-

cult to recognize—of "subacute" and of "latent" scurvy. A recent writer² also remarks that, judged by clinical criteria, scurvy is uncommon in this country. An acquaintance with experimentally produced scurvy, however, indicates that various degrees of deficiency associated with a number of morbid changes can occur without classic symptoms or signs of the disease.

Capillary fragility, leading to the appearance of petechiae, is one of the earliest detectable manifestations of the effects of a scurvy-producing diet in animals. The close analogy between the experimental disease in guinea-pigs and man has suggested that some method of measuring capillary resistance or fragility might be developed for the human organism. An early procedure³ involved observations of the hemorrhagic diathesis produced by constricting part of the arm. An alternative method consists in the application of negative pressure to the surfaces of the skin through a suction cup connected with a mercury manometer and vacuum pump. It has been employed by Dalldorf² at the Grassland Hospital in Vallhalla, N. Y., on a group of children not suffering from any disease known to produce a hemorrhagic diathesis. Many of them were tuberculous, others were sent for observation. In any event they came from poor homes. Judged by their capillary resistance, the incidence of subclinical scurvy was found to be between 35 and 66 per cent. The shortcomings of such methods have frequently been stressed, notably by Hess.⁴ Nevertheless, Dalldorf counts them as of some value. A consistent feature of the measurements of capillary resistance has been the difference between persons. This constitutes a serious limitation to the use of the test, since the values secured in a single reading can have little significance unless the normal for the person is known. Dalldorf believes that the character of the skin itself partly determines the results of the test. The groups studied included dark-skinned southern Europeans, light-skinned nordic types and persons with intermediate complexions, commonly found among Americans. Dalldorf points out in conclusion, that the effects of slight dietary deficiencies on health are not known. Of late years, much has been made of the relationship of mild vitamin C deficiency to dental caries, and it has long been known that patients suffering from scurvy are prone to contract infectious diseases. The effect of a lesser degree of vitamin C deficiency on the resistance to infectious diseases is yet to be determined. These and similar

problems are fully discussed in recent treatises on nutrition. In Drildorf's opinion the prevalence of this dietary stigma among the poorer classes requires further study from the standpoint of public health.

THE CHICAGO OUTBREAK OF AMEBIASIS

Elsewhere in this issue appear two documents relative to the outbreak of amebiasis that developed in Chicago during the summer and fall of 1933. The first of these reports (p. 367) provides a chronology of the incidents associated with the recognition of the nature of the outbreak and the measures employed in attempting to bring it under control. The second report (p. 369) is that of a committee¹ assembled to study the available data with a view to determining the source of the outbreak and to drawing up recommendations for the prevention of similar catastrophes in the future.

The evidence appears to be sufficient to warrant the opinion that this outbreak of amebiasis originated in two hotels as a result of the contamination of the water supply of the hotels with sewage. Thereafter, no doubt, widespread infection of the food handlers and the employees of the hotel in general served to aid in the spread of the infection to guests. The unusual incident recited in the paper by Bundesen, Tonney and Rawlings, in which raw river water was turned by a cross-connection into the water supply of a manufacturing plant, resulting in an outbreak of amebiasis which included also some cases of typhoid, serves as a remarkable control case, to demonstrate the possibilities.

In various places the Board of Health of Chicago, including its president, has been criticized for failure to notify the public sooner of the presence of amebiasis in the hotels concerned, and it has been intimated that this alleged failure bore a definite relationship to the presence in Chicago of the Century of Progress exposition. Attention is called in this connection to the chronology of the incidents concerned in this outbreak, the gradual manner in which necessary facts were perforce developed, and the way in which questionnaires, radio broadcasting and publicity were used to bring to light as many cases as possible in cities outside of Chicago. It is safe to say that in a previous generation the majority of these cases might never have been detected in relationship to the original focus in Chicago. Without such efforts the existence of a widespread epidemic might never have been known. In the present

instance the procedure served to awaken the attending physicians of more than 700 patients in some 206 cities throughout the United States to a realization of the nature of the disease, the necessity for laboratory study, the desirability of avoiding surgical operations, and the specific quality of the various remedies that have been proved to be successful in treating the disease.

Amebiasis has been a rare diagnosis in most Northern communities, so rare indeed that suspicion is now aroused as to the frequency with which it may have been overlooked. Now comes good evidence that from 3 to 5 per cent of our entire population is infected. This evidence justifies strong emphasis on the subject in medical schools, hospitals, medical societies and other places of medical education. At the Cleveland session of the American Medical Association, to be held next June a general scientific meeting will be held devoted wholly to this subject. Several of the authorities who developed the report in this issue of *THE JOURNAL* will take part in the program.

While the report of the committee serves many useful purposes—for example, its listing of standard laboratory technique and standard methods of prophylaxis—its most vital section would appear to be the recommendations concerning sanitary engineering of large buildings and hotels. Notwithstanding the fact that the laws of practically every state and municipality forbid the existence of cross-connections in plumbing which permit sewage or contaminated water supplies to mix with supplies of water for domestic uses, it is apparent that such cross-connections actually do exist in many of these hotels and buildings and that they are a constant menace to the health of human beings. In a survey of water-borne typhoid fever outbreaks, Wolman and Gorman² report that water-borne outbreaks during the past decade have been due as much to laxity in handling water from its source to the consumer as to the use of water from polluted sources. Two thousand and fifty-five cases of typhoid in the United States occurred because of pollution of an apparently safe water as it was being distributed to the consumer. Of these, 1,995, or over 95 per cent, were due to unprotected cross-connections with polluted water supplies. Chlorination may inhibit typhoid organisms but does not seem to control or destroy *E. histolytica*, the cause of amebiasis. Apparently the business of inspection and control of plumbing for such defects is beyond the funds and facilities anywhere available for the purpose. One wonders therefore whether it might not be advisable for every large building or hotel housing and catering to thousands of people daily, to employ its own sanitary officer, responsible jointly to the president of the corporation and to the health officials of the community, with a view to detecting hazards relating to water supply and sewage disposal, food handling, ventilation and similar problems.

¹ The members of the committee were Albert J. Chesley, M.D., secretary, Conference of State and Provincial Health Authorities of North America, Minneapolis; Charles F. Craig, M.D., Colonel U.S. Army, retired professor of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans; Morris Fishbein, M.D., editor of *THE JOURNAL*; Ludwig Hektoen, M.D., director of the John McCormick Institute of Infectious Diseases, Chicago; Thomas Byrd Magath, I.D., M.D., of the Section on Clinical Pathology, Mayo Clinic, Rochester, Minn.; George W. McCoy, M.D., medical director, U.S. Public Health Service, Washington; D. C. Henry E. Meloney, M.D., associate professor of preventive medicine and public health, Vanderbilt University School of Medicine, Nashville, Tenn.; F. W. O'Connor, F.R.C.S., of the Department of Tropical Medicine, Columbia University, New York; Milton Portis, M.D., professor of medicine, Loyola University School of Medicine, Chicago; and Abel Wolman, chief sanitary engineer, Maryland State Board of Health.

² Wolman, Abel and Gorman, A. E. The Significance of Water Borne Typhoid Fever Outbreaks 1920-1930. *J. Am. Water Works A.* 23: 160 (Feb.) 1931.

Finally, it is obvious that there are throughout the United States numerous buildings and hostels with antiquated plumbing incapable of withstanding the stresses likely to be placed on it by the demands of modern congestion. Until such equipment is suitably inspected and brought down to date in accordance with the building and the number of people whom it must serve, there can be no warrant that similar outbreaks may not occur in any place where similar conditions prevail.

ABSORPTION IN INTESTINAL OBSTRUCTION

It is not surprising that the view attributing the cause of death in intestinal obstruction to the absorption of toxic material from the lumen of the intestine was early expressed and has since been held with more or less tenacity. This organ is the locus of vigorous digestive activity brought about by the enzymes of the juices of the pancreas and of the intestine itself. Furthermore, bacteria cause changes in food residues with the production of chemical compounds which, in suitable doses are recognized as toxic. In view of the fact that the intestine is the organ of absorption *par excellence*, it seems reasonable enough to suspect that toxic material entering the body by way of the intestinal epithelium is concerned with the fatal outcome of intestinal obstruction. However, experimental studies have cast considerable doubt on the validity of toxin production in nongangrenous obstruction. Nevertheless, the possibility still exists that the symptoms of this disorder are attributable to an alteration of normal absorption of substances ordinarily present in the intestine.

Experiments designed to elucidate the foregoing thesis have been carried out by Best, Newton and Meidinger.¹ They emphasize the importance of investigating the absorption both above and below the obstruction in studies of this kind. Trypan blue and red, both colloidal dyes, were given to normal animals and to others with intestinal obstructions. In no case could the absorption of the dye be demonstrated. Then methylene blue was introduced into the intestine of normal controls and of experimental animals, some with obstructions in the duodenum and others with obstructions near the terminal ileum. Examination of the urine for the dye led to the conclusion that the rate of absorption from the intestine was essentially the same in the experimental group as in the normal animals. Furthermore, no difference between the rate of absorption above the obstruction and that below could be demonstrated. It appears from these studies that an altered absorption from the intestine is not an invariable consequence of obstruction, the importance of this alleged circumstance as a factor in the cause of death can be questioned.

Best, Newton and Meidinger believe that as a result of the admixture of upper intestinal contents with the material in the intestine farther down, there is formed a substance of unknown nature, the absorption of which is essential for normal cell function. The facts that introduction of vomitus into the intestine through a fistula posterior to a high duodenal obstruction prolongs the life of experimental animals and that obstruction in the distal colon is compatible with life for some time are cited as evidence for this view. The manifold nature of the functions of the intestine—digestion, absorption, excretion, potential influence on acid-base equilibrium, electrolyte and water balance—together with the fact that it harbors a complex bacterial flora inevitably renders difficult both the planning of cogent experiments and the interpretation of clinical observations.

CYTO-INHIBITION OF SERUM THERAPY

Experimenters¹ in the Rockefeller Institute observed two decades ago that tubercle bacilli ingested by leukocytes are apparently protected from the lytic action of the peritoneal antibodies of tuberculo-immune guinea pigs. This immunologic paradox was afterward studied in detail by Rous and Jones² who found that test tube phagocytosis not only protects such micro-organisms as the typhoid bacillus against lysis by homologous specific immune serums but also protects them against certain chemical antiseptics. This protection is apparently due to certain vital factors in the ingesting phagocytes, since cytologic protection ceases on the death of these cells. The New York investigators concluded from their data that serum therapy and chemotherapy might conceivably be ineffective in numerous specific infectious diseases, solely on account of the intracellular location of the infectious agent.

Rous and his colleagues³ have recently extended this paradox to include certain filtrable viruses. Suspensions of embryonic tissue culture cells (rabbit), for example, were inoculated with vaccinia. Both viable and nonviable cells were found to absorb this virus, the thoroughly washed exposed cells causing typical vaccinia lesions on injection into rabbits. The addition of specific immune serum to virus-infected cell suspensions killed or otherwise inactivated all free virus and all virus on or within nonviable tissue cells. The same antiserum was without demonstrable virucidal effect on virus units on or within living cells. Similar protective results of viable tissues were obtained with the filtrable agents causing rabbit fibroma and chicken sarcoma.

Indirect confirmation of the Rous-Jones paradox is currently reported by Schultz and Gebhardt⁴ of Stan-

ford University. In their hands, prophylactic injections of convalescent monkey serum or of hyperimmune horse serum prevents the development of experimental poliomyelitis in monkeys in about one third of the cases. Repeated massive doses of the same antisera, however, given two or more days after intranasal inoculation, are without demonstrable therapeutic effects. Kolmer and Rule's⁵ demonstration of the therapeutic failure of intravenous injections with massive doses of such antiseptics as mercurochrome, methenamine and arsphenamine in experimental poliomyelitis in monkeys is in accord with the Rous-Jones theory. Control tests of the prophylactic efficiency of the same antiseptic have not yet been reported by the Philadelphia investigators.

Current Comment

FURTHER EXPANSION OF RADIO BROADCASTING BY THE AMERICAN MEDICAL ASSOCIATION

Last week attention was called to the special facilities provided by the National Broadcasting Company for broadcasting on health subjects by the American Medical Association. This week we announce the provision of similar facilities by the Columbia Broadcasting System. At present thirty-two additional stations are listed on this hookup, covering the Middle West, Northwest, Southwest and the Pacific Coast. The time of these broadcasts will be each Thursday from 4:30 to 4:45 p. m., Central standard time. The subjects covered will be advice on health, discussions of the relationships of the medical profession to the public, and similar topics. These will be listed in *THE JOURNAL* each week under the heading Association News. It is highly desirable that physicians call the attention of their patients to these broadcasts so as to insure for them the largest possible audience. *THE JOURNAL* here expresses on behalf of the medical profession its deep appreciation to the Columbia Broadcasting System for supplying these facilities without cost to the medical profession.

URINE PROTEINS IN NEPHRITIS

Not many years ago the protein in the urine of nephritic patients was sometimes associated directly with the albuminous constituents of the food intake. The idea that dietary protein can reappear in more than the minutest traces in the secretion of the kidneys had to be abandoned when the modern theory of enzymatic alimentary digestion established itself. On this hypothesis well established now by many facts, the products of absorption are not the dietary proteins, as such, but rather their degradation products. Beyond the alimentary barrier, proteins arise and appear only by resynthesis from nonprotein nitrogenous fragments. It would be almost ridiculous, therefore, to assume that a foreign protein would be reconstituted in the organ-

ism and excreted in its original form. The other direct source of urinary proteins is the blood plasma. It is not necessary to assume that blood proteins traverse the kidneys unchanged in cases of albuminuria of any sort, for it is quite conceivable that somehow they may be changed by the renal structures during the process of excretion. In the case of Bence-Jones proteinuria the protein undoubtedly is unlike the serum proteins. This, however, represents a special case. The nature of the urinary proteins in ordinary albuminuria is now generally regarded as identical with that of serum. Research by Widdowson¹ at the Middlesex Hospital, London, brings added confirmation. Investigations on the nitrogen distribution, racemization, osmotic pressure and specific refraction of urine and serum proteins from nephritic patients indicate that the corresponding urine and serum proteins from any one patient are identical. In ordinary nephritis and in prolonged proteinuria there appears to be no alteration in the structure of the proteins. This fact seems to decide once and for all, Widdowson concludes, that there is no defect in protein synthesis in these cases.

Association News

MEDICAL BROADCAST FOR THE WEEK

Columbia Broadcasting System

A new program arrangement has been concluded through the courtesy of the Columbia Broadcasting System for a weekly broadcast on the Educational Forum from 4:30 to 4:45 p. m. Central standard time, each Thursday, beginning February 1. The program is available to the following stations, subject to station option.

West North Central States		Mountain States	
WCCO	Minneapolis	KLZ	Denver
WNA	Yankton S. D.	KVOR	Colorado Springs
KSCJ	Sioux City, Iowa	KSL	Salt Lake City
KFAB	Lincoln, Neb.	KOH	Reno
WMT	Waterloo, Iowa		
KMBC	Kansas City, Kan.	Pacific States	
WIBW	Topeka	KERN	Bakersfield
KFH	Wichita	KMJ	Fresno
East North Central States		KHJ	Los Angeles
WMBD	Peoria, Ill.	KOIN	Portland
WISN	Milwaukee	KFKB	Sacramento
WBBM	Chicago	KGB	San Diego
West South Central States		KFRG	San Francisco
KOMA	Oklahoma City	KDB	Santa Barbara
KRLD	Fort Worth	KOL	Seattle
WACO	Waco	KFPY	Spokane
KTSA	San Antonio	KWG	Stockton
KTRH	Houston	KVI	Tacoma

The plan of the program is a ten minute health talk, preceded and followed by selections by the studio orchestra. The subject for Thursday, February 8, is "Men's Hearts Fail Them." The speaker will be Dr. W. W. Bauer, director, Bureau of Health and Public Instruction.

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15 Central standard time (5 o'clock, Eastern standard time, 3 o'clock, Mountain standard time and 2 o'clock, Pacific standard time). The subject for Monday, February 5 is "What About Your Blood Pressure?" The speaker will be Dr. Bauer.

Radio Talk from Station WBBM

The American Medical Association broadcasts on Tuesday mornings from 8:55 to 9 o'clock, Central standard time, over Station WBBM (770 kilocycles, or 389.4 meters). The subject for Tuesday, February 6 is "Foods and Resistance."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Elimination of Tuberculous Cattle—Recognizing that California has the largest number of tuberculous animals in its dairy herds of any state, a committee representing the Health Officers' Section of the League of California Municipalities recently adopted a resolution urging the secretary of agriculture of the United States to adopt means to eliminate the dairy surplus through the testing and slaughtering of diseased animals. Insufficient funds have restricted California's control and eradication of bovine tuberculosis, and it is hoped that the government's plan to eliminate surpluses of farm commodities will strengthen the state's program begun in 1895. The committee is composed of Drs. John J. Sippy, Stockton, chairman; Arthur Hieronymus, Oakland, and Herbert F. True, Sacramento.

Society News—The Los Angeles Pathological Society was addressed, January 9, among others, by Dr. Paul E. McMaster on "Suppurative Arthritis Associated with Osteomyelitis," and John F. Kessel, Ph.D., "Streptococci of the Intestinal Tract."—The Orange County Medical Society was addressed November 7, by Dr. Norman J. Kilbourne, Los Angeles, on hemorrhoids.—At a recent meeting of the Sacramento Society for Medical Improvement, Drs. Frank B. Reardon and Frederick F. Gunderson discussed "Subarachnoid Hemorrhage."—A symposium on arthritis was presented before the Alameda County Medical Association, January 15, in Oakland, by Drs. Leonard B. Barnard, Gertrude Moore, Dorothy M. Allen, Hugh G. MacLean, and Charles B. Fowler.—At a meeting of the Los Angeles Surgical Society, January 12, the speakers were Drs. Leo J. Adelstein and George O. Berg on "Surgical Treatment of Syringomyelia," and Kenneth E. Smiley, "Pilonidal Sinus."—Chauncey D. Leake, Ph.D., professor of pharmacology, University of California Medical School, Berkeley, discussed "Medical Caricatures" before a joint meeting of the Hollywood Academy of Medicine and the section on internal medicine of the Los Angeles County Medical Association, January 18.

COLORADO

Society News—A symposium on tuberculosis was presented before the Otero County Medical Society at Fort Lyon, December 5, by Drs. Ralph J. Jones, Benjamin F. Jackson, and Franklin C. Cassidy. Dr. Carl W. Maynard, Pueblo, gave a paper before the society, December 19, on "Anemias of Pregnancy."—At a meeting of the Weld County Medical Society, recently, Dr. Cyrus W. Anderson, Denver, spoke on "Optional Motherhood."

Stream Pollution—A survey of stream pollution in the state was recommended in resolutions adopted at a joint meeting of the Colorado Municipal League and state health authorities December 14. At a special session called by Dr. Samuel R. McKelvey, executive officer, state division of public health, information on stream pollution, gathered by a committee of the state medical board, and statistics of deaths resulting from pollution, compiled according to counties, were considered.

CONNECTICUT

Lectures on Venereal Disease—The state health department recently inaugurated a series of illustrated lectures on venereal disease in civilian conservation camps. An average of 200 men has been reached in each of the twelve camps where the lectures have been given. Plans were being made in December for lectures to be presented in two newly organized camps. Dr. Henry P. Talbot, chief of the division of venereal diseases of the state health department, gave the first twelve talks.

Sale of Parrakeets Prohibited—The Public Health Council voted, December 28, to add a regulation to the state sanitary code prohibiting the sale of parrakeets in Connecticut. The text of the regulation, which became effective January 15, reads:

No person, firm or corporation shall buy, sell or transport within the state of Connecticut birds belonging to that branch of the psittacine family known as parrakeets or love birds.

Recent investigations show that a parrakeet sent to Connecticut last summer was found to contain the psittacosis virus

after its death in August and that psittacosis among human beings was traced to infected parrakeets shipped to the state from California during the last summer and fall. The penalty for violation of the new regulation is a fine of not more than \$100 or imprisonment for not more than three months or both.

DISTRICT OF COLUMBIA

Health at Washington—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended January 20 indicate that the highest mortality rate (21.3) appeared for Washington and for the group of cities as a whole, 12.3. The mortality rate for Washington for the corresponding week last year was 18.5, and for the group of cities 12.9. The annual rate for eighty-six cities for the three weeks of 1934 was 12.7, as compared with a rate of 13.3 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Medical Bills in Congress—Bill Introduced H. R. 6952, introduced by Representative Norton (by request), New Jersey, proposes to amend the optometry practice act of the District of Columbia by authorizing the board of optometry to make rules, consistent with the provisions of the optometry act, governing applicants and applications for admission to licensure and to govern the practice of optometry. These rules must be submitted to the commissioners of the District of Columbia for approval. The bill further authorizes the board of optometry to revoke the license of any licensee guilty of violating any rule, order or regulation promulgated by the board, and the right to revoke or suspend a license of a licensee convicted of any criminal offense who is found by the board to be grossly incompetent, afflicted with a contagious disease, a habitual drunkard, or guilty of unprofessional conduct. The board of optometry is to have power to determine what acts constitute unprofessional conduct.

GEORGIA

No Diphtheria Deaths in Savannah in 1933—For the first time in Savannah no deaths were reported from diphtheria during the calendar year 1933. A large number of infants and young children have been immunized in recent years.

Personal—Dr. Charles C. Harrold Macon, has been named chairman of the state committee of the American Society for the Control of Cancer.—Dr. Millard E. Winchester, Atlanta, has been appointed health officer of Glynn County, succeeding the late Dr. Henry L. Akridge.

IDAHO

Society News—Dr. Orval F. Swindell, Boise, has been appointed state tuberculosis adviser under the terms of the tuberculosis hospitalization act. He will supervise diagnosis and treatment in the state wards maintained at Coeur d'Alene and Boise for early cases.—Dr. John H. Einhouse, Moscow, addressed the Nez Perce County Medical Society, Lewiston, Nov. 15, 1933, on "Treatment of Acne Vulgaris."—At a meeting of the Canyon County Medical Society, Nampa, December 15, speakers were Drs. William Wilson, Portland, on obstetrics, Ernest Boyland, Portland, diseases of the heart, and Orval F. Swindell, Boise, tuberculosis.—Drs. Joseph A. Pettit and John H. Fitzgibbon, Portland, Ore., addressed the South Side Medical Society, Rupert, December 8, on "General Surgical Principles of the Oral Cavity and the Medical and Systemic Background of Its Lesions," and "Lesions of the Esophagus," respectively.

ILLINOIS

Tumor Clinic—Dr. Joseph Colt Bloodgood, clinical professor of surgery, Johns Hopkins University School of Medicine, Baltimore, was the guest speaker at Veterans Administration Facility, Hines, January 23, at a tumor clinic. His subject was "The Evolution of the Treatment of Cancer as I Have Observed It." Other speakers included:

Dr. Max Cutler, Chicago, "Indications and Limitations of Radium in the Treatment of Cancer."

Dr. Paul F. Brown, Hines, "Operability and Inoperability of Tumors." Dr. Linnaeus H. Prince, Hines, "Clinical Laboratory and Autopsy Activities, 1933."

Dr. John W. Turner, Hines, "Organization of Tumor Clinic." Dr. S. E. Owen, Ph.D., Chicago, "Biological Diagnosis of Teratomas."

Dr. Gilbert Fitz-Patrick, Chicago, showed the Cantani Cancer Film, and Dr. Thomas Hugh Scott, manager of the facility, introduced the speakers.

Chicago

Dr Oliver to Give Hektoen Lecture—Dr Jean R. Oliver, professor of pathology, Long Island College of Medicine will deliver the tenth Ludvig Hektoen Lecture of the Frank Billings Foundation, February 23, on "The Problem of Architectonics in Terminal Bright's Disease." The lecture will be given in the Chicago Woman's Club at 8 o'clock.

Society News—The Chicago Surgical Society was addressed February 2, among others, by Drs Edward Starr Judd, Rochester, Minn., and Dean Lewis, Baltimore, on "Present Status of the Surgical Treatment of Peptic Ulcer" and "Chronic Cystic Mastitis and Its Relation to Ovarian Hormones," respectively. At a meeting of the Chicago Council of Medical Women, February 2, Drs Marie Wessels spoke on "A Social Problem of Gynecology and Obstetrics" and Mary G. Schroeder, "The Relation of Insanity to Birth Control."

Rush College Presents Program—The department of otolaryngology of Rush Medical College will offer the clinical demonstrations and scientific program of the Chicago Laryngological and Otolological Society, February 5, as follows:

Carcinoma of the Larynx Drs Louis T. Curry and Linden J. Wallner
Surgical Treatment of Dacryocystitis and Primary Skin Grafts in Radical Mastoid Surgery Dr George E. Shambaugh Jr.
Problems in the Surgical Treatment of Septum Irregularities Dr Thomas W. Lewis
Vertigo and Deafness Following Cerebral Concussion Dr Daniel B. Hayden
Electrocautery in the Treatment of Allergic Noses Dr George A. Torrison
Pathology of Otosclerosis Dr Elmer W. Hagens
Diathermy in the Treatment of Some Nose and Throat Conditions Other Than Tonsils Dr Clifford L. Dougherty
Diathermy in the Treatment of Chronic Tonsillitis Dr William J. Yonker

KENTUCKY

University News—The University of Louisville School of Medicine is building an addition to its present plant to give increased space for all laboratory courses, research laboratories in all departments, and special libraries.

Bills Introduced—S 4 proposes to prohibit a physician from testifying "concerning a communication made to him in his professional character, by his patient, or his advice thereon without the patient's consent." H 109 proposes to levy a tax of 10 per cent of the selling price on among other things the sale of proprietary and patent medicines, antiseptics and deodorants and cosmetics. H 189 proposes to abolish the office of state supervisor of chiropractors.

MARYLAND

Free Chest Clinics—The Maryland Tuberculosis Association plans to conduct more than 100 free chest clinics in counties throughout the state during the first six months of its fiscal year, which began on Oct. 1, 1933. The examining physicians include the superintendents of the various tuberculosis sanatoriums of the state, as well as other tuberculosis specialists.

Personal—Dr George Walker, Baltimore has been elected a member of the board of trustees of the Maryland Academy of Sciences, succeeding the late Charles C. Plitt, Sc.D.—Dr George W. H. Hemmeter has been appointed full time medical health officer in the Baltimore Health Department. This appointment is the second of its kind in the department, the position having been created within recent months. Dr Anthony L. Rettaliata was the first appointed.—Dr Lee J. Volenick has been appointed director of the Nursery and Child's Hospital, Baltimore, effective January 1, succeeding Dr Frederick B. Dart, who has resigned to join his father in practice in Connecticut.—Dr Joseph L. Valentini has been appointed coroner at large for Baltimore succeeding the late Dr George C. Blades.

Rare Book Presented to Society—A copy of "An Essay on the Nature Cause and Cure of a Disease Incident to the Liver" by Dr John Crawford who died in Baltimore in 1813 was presented to the Osler Historical Society by Mr Louis H. Dielman at a meeting, January 15. The book was published in London in 1772. Dr Jacob Hall Pleasants sketched the life of Dr Crawford and Dr John Rathbone Oliver reviewed the recent sesquicentennial celebration of the Harvard Medical School Boston. Born in Ireland in 1746, Dr Crawford received his degree in medicine at the University of Leiden. After several years in England and South America he went to Baltimore where he was prominent in the founding of the Baltimore General Hospital in 1801, the penitentiary in 1802 and the Baltimore Library. He conducted courses in natural history at the College of Medicine in 1811 and 1812 of which an

introductory lecture on the "Cause, Seat and Cure of Diseases" is extant. Active in the affairs of the Medical and Chirurgical Faculty of Maryland, he was famed for his research into the cause of disease, conceiving as early as 1790 the idea of a "living contagium." Dr Crawford's library is preserved at the University of Maryland.

MASSACHUSETTS

Society News—Speakers before the Middlesex South District Medical Society in Waltham, February 20, will be Drs Roy D. Halloran, on "Metropolitan State Hospital—Purpose and Development", Malcolm J. Farrell "Demonstration of Two Similar Psychotic Entities Postencephalitis Lethargica and Dementia Praecox, Catatonic Type", Philip F. Hilton, "Demonstration of Injection Treatment of Varicose Veins in a Mental Hospital Population," and Clifford D. Moore, "Mental Disease Occurring in the Course of Physical Disease, with Particular Reference to Pulmonary Tuberculosis."—Dr Alonzo K. Paine, Boston, was elected president of the New England Obstetrical and Gynecological Society at its fifth annual meeting in Boston, November 22.

Sunday Afternoon Lectures—January 7 marked the opening of a series of twelve public medical lectures at Harvard Medical School on Sunday afternoons. Dr Richard M. Smith, assistant professor of child hygiene, spoke on "How Do Your Children Grow?" Other lectures have been delivered by Drs Francis W. Palfrey, assistant professor of medicine, on "Hygiene of Middle Life", Tracy B. Mallory, instructor in pathology "Cancer," and John Homans, assistant professor of surgery "Varicose Veins and Varicose Ulcers." Subsequent speakers will be

Philip Drinker, Ch.E., associate professor of industrial hygiene "The Air We Breathe," February 4.
Dr Frank T. Fulton, Providence, R.I. "How to Budget the Reserve Strength of the Heart," February 11.
Dr Walter Bauer, assistant professor and tutor in medicine "Arthritis," February 18.
Dr Varaztad H. Kazanjian, professor of clinical oral surgery, "Dentistry's Contribution to the Repair of Face and Jaw Deformities," February 25.
Dr Walter L. Mendenhall, professor of pharmacology, Boston University Medical School "Tobacco," March 4.
Dr Alice Hamilton, assistant professor of industrial medicine "Dangerous Trades," March 11.
Dr Frederick C. Irving, professor of obstetrics "The Change of Life," March 18.
Dr G. Philip Grabfield, instructor in pharmacology "Headaches and Headache Remedies," March 25.

Bills Introduced—S 162 proposes to provide for the licensing of chiropractors by the board of registration in medicine, assisted by two chiropractors, and to regulate the practice of chiropractic. Chiropractic is defined to mean the external treatment of the human spine by mechanical or manual means. H 712 proposes a procedure to secure the payment of the charges of any hospital, incorporated as a charitable corporation or under public control, for services arising out of motor vehicle accidents, out of the proceeds of motor vehicle liability policies and bonds. H 755 proposes to amend the medical practice act so as to provide that applicants for licenses not only must have received the degree of doctor of medicine from a legally chartered medical college having the power to confer degrees in medicine but also must have had all of their medical school work in an institution having the power to confer degrees in medicine. H 731 proposes to make it a ground for revoking the certificate of registration of a registered pharmacist for the holder to "display, or advertise for sale, or permit to be displayed or advertised for sale, alcoholic liquors sold by him." H 896 proposes that a child from a household where a person is ill with smallpox, diphtheria, scarlet fever, measles, or any other infectious or contagious disease, shall not attend any public school during such illness or exposure until a physician or the local board of health certifies that the danger of conveying disease by the child is passed. H 1198 proposes to create a board of examination and registration for magnetic healers. Apparently, an applicant for a license to practice magnetic healing need prove no qualifications other than an ability to examine "nerve conditions by his magnetic power." A certificate to practice magnetic healing is to entitle the holder to practice magnetic healing but it shall not authorize its holder to administer drugs or perform surgical operations with the use of instruments provided that nothing in this act shall be construed to prohibit any legally registered magnetic healer from practicing surgery after having passed a satisfactory examination therein before the state board of registration in medicine. The bill states that the system method or science commonly known as magnetic healing is defined to be the science of reviving and producing life and circulation in the nerve system and cells so as to heal all nerve affections.

MINNESOTA

Society News—At a meeting of the Hennepin County Medical Society, Minneapolis, January 17, amebic dysentery was discussed by William A. Riley, Ph.D., and Dr. Harry W. Christman, and agranulocytosis by Drs. Rudolph C. Loge and Frank H. Hacking.—The Minnesota Pathological Society devoted its meeting, December 19, to a discussion of amebic dysentery.

Health Survey—A health survey will be carried on in Minneapolis as a project of the Civil Works Administration. Newspapers announce information will be gathered through a house to house canvass in an effort to determine what proportion of reportable ailments are actually recorded officially. Food handling establishments will also be inspected for sanitary conditions and to ascertain whether they have been properly licensed.

MISSISSIPPI

Bills Introduced—S. 53 proposes to amend the privileged communication statute by providing that it shall not apply to any case in which the mental or physical condition of the patient is put in issue in any civil proceeding by the patient or by his personal representative, heirs or distributees. S. 125 proposes to abolish the Jackson Charity Hospital and to provide for the disposition of all the real and personal property of that hospital.

NEBRASKA

Society News—Drs. Roy W. Fouts and Joseph A. Henske, Omaha, addressed the Madison Six-County Medical Society, December 12, on "Treatment of Superficial Lesions" and "Rheumatic Fever in Children," respectively.—The Fifth Council District Medical Society recently held two meetings, one at Columbus, November 26, and one at Fremont, December 5. Speakers at Columbus were Drs. Anders P. Overgaard and Rodney W. Bliss, Omaha, on "Use and Value of Heavily Filtered X-Rays" and "Complications of Peptic Ulcer," respectively. At Fremont, Dr. John Buis, Pender, discussed "Streptococcus Infection of the Hip Joint" and Dr. George A. Haslam, Fremont, reported a case of intussusception.—Drs. Adolph Sachs and Benjamin Carl Russum, Omaha, conducted a cardiac clinic before the Otoe County Medical Society, Nebraska City, January 8.—Speakers at a meeting of the Omaha-Douglas County Medical Society, January 23, were Drs. Arthur C. Stokes, on "Newer Conceptions of Blood Pressure Readings with Relationship to Body Surface and Weight," Herman F. Johnson, "Artificial Impaction of Fractures in the Neck of the Femur," and Albert P. Condon, Pathology and Treatment of Gallbladder Lesions.

NEW HAMPSHIRE

Second Child Health Conference—The second state conference on child health was held in Concord, January 23, called by Governor Winant. A symposium on physical, mental and social aspects of child health was held in the morning, speakers including Drs. Charles H. Parsons, Concord, and Douglas A. Thom, Boston. The afternoon was devoted to a discussion of malnutrition.

NEW JERSEY

Dr. Joseph Stokes Honored—Dr. Joseph Stokes, Moorestown, was the guest of honor at a banquet given by the Burlington County Medical Society, December 19, marking his completion of fifty years of medical practice. Dr. Joseph M. Kuder, Mount Holly, was toastmaster and speakers included Drs. Alfred Stengel, Philadelphia, Marcus W. Newcomb, Browns Mills, vice president, Medical Society of New Jersey, George E. de Schweinitz, Philadelphia, Joseph E. Roberts, Jr., Camden, Nathan Thorne, Moorestown, and Mr. David Roberts, Moorestown. One hundred and sixty guests were present. Dr. Stokes is the fourth of five generations of his family to be physicians; he has two sons practicing medicine, Dr. Samuel Emlen Stokes, Moorestown, and Dr. Joseph Stokes, Jr., Philadelphia.

Bills Introduced—A. 4 proposes to require a thorough physical examination, including, if necessary, a "stereoscopic x-ray photograph" of the chest, of all students admitted to state normal schools and teachers' colleges and of persons applying for certificates to teach in the public schools. Should the examination reveal evidence of tuberculosis, the diseased person may not attend the normal school or obtain a teachers' certificate until satisfactory proof of recovery is furnished. A. 5 proposes that whenever any board of education shall

have reason to believe that any teacher is in ill health, it shall require the teacher to submit to a thorough physical examination. If the examination reveals the existence of a communicable disease the teacher is to be ineligible for further teaching service until satisfactory proof of recovery is furnished. A. 22 proposes to authorize the department of public health to license persons to practice beauty culture. Such licensees, among other things, are to be permitted to remove superfluous hair "by the use of mechanical or electrical apparatus or appliances." A. 28 proposes that no hospital supported wholly or partly at public expense shall hereafter receive any compensation for medical, dental or pharmaceutical services rendered while operating a clinic to which the public is invited.

Society News—The first scientific meeting of the New Jersey Gastro-Enterological Society was held in October in Newark, with Drs. Sigurd W. Johnsen, Passaic, and Louis L. Perkel, Jersey City, as speakers, on "Clinical and Roentgenological Study of 100 Cases of Constipation" and "Malignancy of the Gastro-Intestinal Tract in Young Adults," respectively.—Dr. William H. Park, director of laboratories, New York City department of health, addressed the Bergen County Medical Society, December 12, on "The Public Health Aspects of Diphtheria" and Dr. Stanley H. Nichols, Long Beach, on the public health program of the state medical society.—A symposium on cancer in the female pelvis was presented before the Camden County Medical Society, December 5, by Drs. Charles F. Hadley, Gordon F. West and Edward A. Y. Schellenger, Jr.—Speakers at the meeting of the Atlantic County Medical Society, December 8, were Drs. George P. Muller, Philadelphia, on acute conditions in the abdomen, and George A. Wyeth, New York, on electrosurgery in cancer.—The staff of Brynmore Hospital presented the program of the Hudson County Medical Society, Jersey City, January 2. Among other subjects presented, Dr. William Antopol and his associates demonstrated with necropsy material the end-results of essential hypertension.

NEW YORK

Bill to Authorize Hospital Insurance—A bill proposing to amend the state insurance laws to permit establishment of group payment plans of hospital care was introduced in the state legislature, January 24. The measure is the outgrowth of a study made by the United Hospital Fund of New York, as a result of which a group plan was proposed to the state commissioner of insurance who held that the existing law does not permit the establishment of such plans (THE JOUR. A. M. A. Aug. 26, 1933, p. 718), and the present bill is designed to remove this obstacle.

Bills Introduced—S. 115 proposes to create a board of hairdressers and cosmetologists and to regulate the practice of hairdressing and cosmetology. S. 155 and A. 128, to amend the medical practice act, proposes to permit the board of regents to restore a license that has been forfeited because of commission of a felony if the former licensee is pardoned by the governor of the state or by the President of the United States of the felony of which he was convicted. The present law does not permit the board to restore such a license if the person has been convicted of a felony committed in his professional capacity. A. 77 to supplement the medical practice act, proposes to prohibit any physician or any other person or corporation from giving away, selling or offering to give away or sell any article bearing on it or annexed thereto any mark or symbol "pertaining in any way to the advertising of medical care or pertaining to any inducement of whatever nature respecting the furnishing or offering of medical care by means of such advertising." The bill proposes too to make it unlawful for any person or corporation other than a duly licensed physician to employ any person other than a licensed physician for the practice of medicine. The latter prohibition however is not to be construed to apply to the practice of medicine in the lawful operation of a hospital, dispensary, or other legally incorporated institution. S. 45, A. 141 and A. 169, to amend the workmen's compensation act propose in effect, to make compensable all occupational diseases contracted in the course of an employment covered by the act.

Report of Committee on Compensation Abuses—A medical committee appointed by Governor Lehman early in 1933 to investigate abuses in connection with workmen's compensation laws submitted its report December 30. The study disclosed that under the present laws the injured workman has often failed to receive adequate medical care, the honest employer has been forced to pay increased insurance costs and the insurance carriers have lost money because they have been unable to estimate actuarial risks accurately. Two kinds of

abuses are distinguished in the report, those due to defects in the law and those chargeable to the medical profession. The report recommends that injured workmen be given the right to choose their own physicians from a roster certified by the county medical society and approved by the industrial commissioner. When the employee exercises this right of free choice, however, the employer or insurance carrier should have the right to have the patient examined periodically by its own physicians and in some cases even to provide different medical care. The report suggests that a medical advisory and appeal board, composed of three physicians, be created in each compensation district, the members to be appointed by the industrial commissioner from nominations made by the medical societies of the district. In addition the committee urged that at least one physician be included on the state industrial board to which compensation cases are appealed. Complete elimination of medical practice by insurance carriers, except for a staff of medical inspectors, is urged as a check on the practice of "undercutting and underbidding." Other recommendations included in the report concerned standardization of minimum fees, creation of an agency to arbitrate disputed bills, licensing of compensation medical bureaus, previously called compensation clinics, and the continuance of a committee to observe the operation of the revised law with a view to recommending correction of faults which may be revealed by subsequent experience. The committee was made up of five physicians representing the New York Academy of Medicine, as follows: Drs Eugene H. Pool, chairman, Frederic W. Bancroft, George Baehr, Adrian V. S. Lambert and Charles A. McKendree, and five representing the Medical Society of the State of New York, as follows: Drs David J. Kaliski, New York, Thomas A. McGoldrick, Brooklyn, Frederick M. Miller, Utica, Harry R. Trick, Buffalo, and Frederick S. Wetherell, Syracuse. Dr Lambert served as chairman of a subcommittee on medical problems of a committee headed by Howard S. Cullman, New York, which made a report on abuses of workmen's compensation laws in 1932 during President Roosevelt's incumbency as governor of New York (THE JOURNAL, March 19, 1932, p. 1000).

New York City

Dr Wynne Accepts Position with Milk Institute—Dr Shirley W. Wynne, formerly health commissioner, has accepted the presidency of the Greater New York-New Jersey Milk Institute, an organization of milk dealers in the metropolitan area, according to the New York Times. Dr Wynne's duties will be largely educational among producers, dealers and consumers and he will represent the institute at hearings of the State Milk Control Board. The announcement stated that Dr Wynne will also engage in medical practice.

Society News—A symposium on plastic surgery was presented before the International and Spanish-Speaking Association of Physicians, Dentists and Pharmacists, December 15, by Drs Vilray P. Blair, St. Louis, and Joseph Eastman Sheehan and Victor H. Sears, D.D.S., New York.—Dr Russell M. Wilder, Rochester, Minn., discussed the Role of the Parathyroids in Health and Disease before the Bronx County Medical Society, December 20.—Dr Louis Fischer addressed the New York Society of Orthodontists, November 20, on "Interrelationship Between Orthodontia and Pediatrics".—Dr Karen Horney, Chicago, among others, addressed the New York Neurological Society in a joint meeting with the section of neurology and psychiatry of the New York Academy of Medicine, January 9, on "Concepts and Misconceptions About the Principles of the Psychoanalytic Method".—Among speakers who addressed the Society for Experimental Biology and Medicine, December 20, were Dr Sidney D. Kramer and M. Schaeffer, on "Experimental Poliomyelitis: Active Immunization with Neutralized Mixtures of Virus and Serum." Drs Leslie J. Webster and George L. Fite, "A Contribution to the Etiology of Encephalitis: Differentiation of Encephalitis by Protection Test," and L. N. Ellis, Ph.D., "Experimental Evidence of an Additional Substance Essential to Mammalian Nutrition."—Drs Soma Weiss, Boston, and Hugo Roesler, Philadelphia, addressed the committee on cardiac clinics of the heart committee of the New York Tuberculosis and Health Association at a meeting at the New York Academy of Medicine, January 23, on "The Role of Cardiovascular Reflexes in the Precipitation of Syncope and Some Aspects of Cardiovascular Roentgenology" respectively.—Dr Leonard G. Rowntree, Philadelphia, addressed the Medical Society of the County of Kings, January 16, on "Recent Advances in Our Knowledge of Endocrine Diseases," and Dr John L. Bauer delivered his inaugural address as president of the society on "Medical Problems."—Dr Louise D. Larimore and Walther C. A. Steffen, among others, addressed the

Queensboro Surgical Society, January 15, on "Carcinoma of the Breast: Pathology and Review of Cases" and "Congenital Pyloric Stenosis," respectively.—Dr Russell L. Cecil delivered an afternoon lecture before the Medical Society of the County of Queens, Forest Hills, January 5, on rheumatic fever.

OHIO

Graduate Lectures in Cleveland—Graduate lectures sponsored by the Cleveland Academy of Medicine during February have been announced as follows:

February 2 X-Ray Diagnosis of Diseases of the Gallbladder Dr. Edgar P. McNamee
February 9 Treatment of Diseases of the Gallbladder Dr. Robert S. Dinsmore, Jr.
February 16 Disease of the Pancreas Dr. Vernon C. Rowland
February 23 Diseases of the Appendix Dr. Carl H. Lenhart

Art and Hobby Exhibit—The Cleveland Academy of Medicine held its second art and hobby exhibit, December 15, for members and December 17 for the public. Nearly seventy-five physicians displayed either their own handicraft or collections of interest in various fields. Paintings in oil and water colors, drawings, sculpture, photographs, wood carving, mechanical equipment, furniture design and hand made jewelry were included in the displays of original work. Collections were shown of books, oil paintings, prints and etchings, guns and swords, coins, stamps, photographs, trophies, stethoscopes and terrariums. Several physicians had displays in more than one category. Among the exhibitors were Drs. Henry J. John, Louis J. Karnosh, W. James Gardner, Gerald S. Shibley, Harold V. Cole and Howard Dittick.

OREGON

Dr Weeks Honored—Dr. John Elmer Weeks, Portland, professor emeritus of ophthalmology, New York University, and Bellevue Hospital Medical School, was the guest of a group of medical friends at a dinner, December 5, in honor of his eightieth birthday, which occurred in August 1933. Dr. Frederick A. Kiehle presided and Drs. Hugh Cabot, Rochester, Minn., Ralph F. Davis and Ralph A. Fenton made complimentary addresses.

PENNSYLVANIA

Society News—Dr. Eldridge L. Eliason, Philadelphia, addressed the Luzerne County Medical Society, Wilkes-Barre, January 3, on "Indigestion—Its Surgical Significance." Dr. Peter P. Mayock, Wilkes-Barre, addressed the society, December 21, on "Renal and Ureteral Anomalies."—Speakers who addressed the Pittsburgh Academy of Medicine, January 23, were Drs. Thomas B. McCollough on "Surgical Treatment of Early Meningitis of Otic Origin," Kurt Semsroth, "Leukemic Reticulo-Endotheliosis and Its Relation to Acute Leukemia," and David Ben Martinez, "Use of Sodium Alurate in Obstetrics."—Dr. William D. Stroud, Philadelphia, addressed the Berks County Medical Society, Reading, January 10, on "Coronary Artery Disease."

Philadelphia

The Thomas Lecture—Dr. Henry G. Bugbee, New York, delivered the annual B. A. Thomas Lecture of the Philadelphia Urological Society, January 22, on "Renal Tuberculosis as a Local Manifestation of General Tuberculosis," at the College of Physicians of Philadelphia.

Symposium on Pernicious Anemia—The section on general medicine and the section on medical history of the College of Physicians of Philadelphia presented a symposium on pernicious anemia at a combined meeting, January 24. Dr. Esmond R. Long discussed "Thomas Addison and His Discovery of Idiopathic Anemia," Drs. Harold W. Jones and Leandro M. Locantini, "Evolution of Views Concerning the Bone Marrow Changes in Pernicious Anemia" and Dr. George R. Minot, Boston, "Remarks Concerning the Discovery of Liver Feeding in Pernicious Anemia."

The Medical Profession and the Public—The College of Physicians of Philadelphia and the American Academy of Political and Social Science will hold a joint meeting, February 7, at which the subject of discussion will be "The Medical Profession and the Public: Currents and Countercurrents." The public is invited. At the morning session speakers will be James H. S. Bossard, Ph.D., professor of sociology, University of Pennsylvania, "A Sociologist Looks at the Doctors," Dr. Nathan B. Van Eeten, New York, "Abuses of Medical Charity and the Free Services of Physicians," and Edgar Sidenstricker, New York, "Medical Practice and Public Need."

At the afternoon session the following addresses will be presented

Dr Henry E Sigerist Baltimore Historic Developments European Experience in Medical Organization
Dr Albert Grant Fleming Montreal Que Canadian and British Experience in the Economics of Medical Practice
Dr Roger I Lee Boston The General Practitioner His Place in the Medical Profession
Michael Davis Ph D Chicago, A Physician's View of the Medical Problem

Speakers at the evening session will be

Dr Thomas Parran Jr state health officer of New York Albany Tomorrow's Health Services
Dr Morris Fishbein Chicago editor of THE JOURNAL The Doctor and the State
William Trufant Foster II D Newton Mass Doctors Patients and the Community

RHODE ISLAND

New Low Death Rate—Preliminary reports indicate that the death rate in Rhode Island for 1933 was 11, the lowest recorded since 1855 and believed to be the lowest ever occurring in the state. The birth rate, 14.2 was also the lowest in the history of the state. The actual number of deaths in the state in 1933 was 7,831, as compared with 8,088 in 1932. There were 10,165 births, compared with 11,186 in 1932.

Society News—Dr Lewis B Porter Providence addressed the Rhode Island Ophthalmological and Otolological Society December 14 on 'The Lingual Thyroid'.—Dr Varatid H Kazanjian Boston, addressed the Providence Medical Association, January 1, on 'Injuries of the Face and Jaws'.—Leonard Carmichael, Ph D of Brown University Providence delivered an address at the State Hospital for Mental Diseases Howard, January 29 on 'Development of Behavior Before Birth'.

SOUTH CAROLINA

Bill Introduced—H 1309 proposes to create a board of cosmetic art examiners and to regulate the practice of hair dressing and cosmetology.

SOUTH DAKOTA

Personal—Dr Lottie Grace Bigler Yankton has been appointed director of child hygiene of the state board of health.—Dr Albert H Speers, physician at the Sisseton Wahpeton Indian reservation since 1920 has retired after twenty-five years in the Indian service. His successor will be Dr Harry R Taylor of the Cheyenne Arapaho reservation, Concho Okla.

Society News—Dr James T Priestley Jr Rochester Minn, addressed the Aberdeen District Medical Society Aberdeen, January 9, on modern treatment of prostatic obstruction and Dr Charles N Spratt Minneapolis presented motion pictures on eye operations.—At a meeting of the Seventh District Medical Society, Sioux Falls, January 12, Dr Joseph C Ohlmacher, director of the state laboratory Vermillion discussed control of typhoid epidemics and Charles A Hunter Ph D, assistant director of the laboratory showed motion pictures taken during the epidemic in Chamberlain in 1933.—The Watertown District Medical Society met in Watertown in December with Dr Orwood J Campbell Minneapolis as guest speaker on cancer of the breast.

VIRGINIA

Bill Introduced—A bill introduced in the House of Delegates, January 24 by Representative English proposes to prohibit the sale of bay rum except on the prescription of a licensed physician.

WEST VIRGINIA

Bills Introduced—H 204 XX proposes among other things, that a physician may not prescribe a greater quantity of liquor at one time than, in the judgment of the physician will last the patient for thirty days, when used as directed. S 86 XX and H 225 XX propose to authorize municipalities to levy an annual privilege tax on persons engaged in the practice of any profession.

WYOMING

Society News—At a meeting of the Northwestern Wyoming Medical Society in Lovell, December 7 the speakers were Drs Evald Olson, Meeteetse, on 'Rifle Shot Wound Complicated with Myelitis', Thomas B Croft Lovell 'Compound Fracture Complicated with Tetanus,' and William W Horsley, Lovell, 'Fracture of the Scapula'.—Dr Emmett R Johnson of the staff of the U S Veterans Facility number 86 presented a paper on spinal anesthesia before the Sheridan County Medical Society December 12 and Dr Richard W Soper showed a film on the same subject.

GENERAL

Meeting of Anatomists—The fiftieth session of the American Association of Anatomists will be held at the University of Pennsylvania School of Medicine, March 29-31. Members wishing to present papers and demonstrations must notify the secretary not later than February 17.

News of Epidemics—Scarlet fever was reported to be epidemic in Grand Rapids, Mich. January 14, in addition to widespread influenza and pneumonia.—Twenty one cases of diphtheria occurred in Memorial Hospital, Albany N Y, within about two days in December. The hospital was quarantined for forty eight hours.—Measles was reported to be epidemic in El Paso, Texas, early in January. 114 cases were reported in the first four days of the month.

Special Board Examinations—The American Board of Otolaryngology announces that examinations for its certificate will be held during the annual session of the American Medical Association in Cleveland June 11 during the meeting of the Pacific Coast Oto Ophthalmological Society in Butte, Mont, July 16, and preceding the meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago, September 8. Applicants for certificates should write Dr William P Wherry, 1500 Medical Arts Building Omaha. The American Board for Ophthalmic Examinations announces that if a sufficient number of candidates are interested an examination will be held at the Butte meeting of the Pacific Coast Oto Ophthalmological Society July 16. Applicants should communicate immediately with the secretary Dr William H Wilder 122 South Michigan Avenue, Chicago.

The President's Birthday Parties—More than 5,000 balls were organized throughout the country in celebration of President Roosevelt's birthday January 30 for the benefit of the Warm Springs Foundation Warm Springs Ga. of which he is president. The foundation hopes to extend its work in the treatment of victims of infantile paralysis on a national scale with the endowment which the committees hoped to raise as a tribute of the American people to the President. Begun in 1926 by Mr Roosevelt and a group of associates as a non-profit-making institution Warm Springs has never had provision for nonpaying or part paying patients. The plant centers about a glass enclosed swimming pool for patients and an open pool for the public and Georgia Hall the administration building recently presented by the people of Georgia as a tribute to the President. Around these are cottages, play rooms and a hospital.

Society News—The fifth congress of the Pan American Medical Association will be in the form of a sixteen day cruise to several Latin American countries, leaving New York March 14 on the S S *Pennsylvania*. During the trip from Havana to Caracas scientific sessions will be held and a one day program will be presented in Venezuela. Dr Joseph Jordan Elller, 745 Fifth Avenue New York is executive secretary of the association.—The next annual meeting of the Association of American Physicians will be held at the Chalfonte-Haddon Hall, Atlantic City, N J May 1-2.—Dr Raymond W Bradshaw Oberlin Ohio was elected president of the American Student Health Association at its annual meeting in Chicago December 27-28.—Dr Otis F Lamson Seattle was elected president of the North Pacific Surgical Association at its annual meeting in Victoria B C December 1 and Dr William K Livingston Portland Ore secretary.

Southern Graduate Assembly—The fiftieth annual session of the Mid-South Post Graduate Medical Assembly, formerly the Tri-States Medical Association of Mississippi, Arkansas and Tennessee will be held in Memphis Tenn February 13-16. The following speakers among others will be presented.

Dr Albert C Furstenberg Ann Arbor Mich Acute Suppurations of the Mouth Pharynx and Cervical Regions
Dr Francis M Pottenger Monrovia Calif Management of the Tuberculous Patient Evaluation of the More Recent Methods of Treatment of Tuberculosis
Dr Fred L Adair Chicago Intracranial Injuries of the Fetus

Medical Bills in Congress—Bills Introduced S 2374, introduced by Senator George, Georgia, proposes to provide additional benefits for veterans. It provides that in cases in which service connection was established for any disability under the provisions of section 200 of the World War Veterans' Act, which service connection was severed by the act approved March 20, 1933, that such service connection be reestablished. It further provides that any World War veteran employed in the active military or naval services between April 6, 1917, and Nov. 11, 1918, not dishonorably discharged, in need of hospitalization or domiciliary care, who is unable to defray the necessary expenses therefor, is to be furnished such hospitalization or domiciliary care in a Veterans' Administration facility within the limitations existing in such facilities, irrespective of whether the disability is due to service. A statement by the veteran that he is unable to pay for the needed services must be accepted by the Administrator of Veterans Affairs as sufficient evidence of that inability. The following bills provide similar benefits: H R 6849 and H R 7134 introduced by Representative Douthett, Pennsylvania; H R 6899 introduced by Representative Disney, Oklahoma; H R 6911 introduced by Representative Moran, Maine; H R 7018 introduced by Representative Chase, Minnesota; H R 7081 introduced by Representative Connolly, Pennsylvania; H R 7093 introduced by Representative Rogers, Oklahoma; H R 7136 introduced by Representative Jenkins, Ohio; H R 7137, introduced by Representative Swick, Pennsylvania; H R 7142, introduced by Representative Jeffers, Alabama; H R 7143 introduced by Representative McKeown, Oklahoma; H R 7154 introduced by Representative Ransley, Pennsylvania; H R 7258, introduced by Representative Johnson, Oklahoma; and H R 7261, introduced by Representative McLeod, Michigan. Senator Reed, Pennsylvania, has also proposed an amendment to H R 6663, the Independent Offices Appropriation Bill, embodying the provisions of the bills discussed above, conferring additional benefits on veterans. S 2244, introduced by Senator Copeland, New York, and H R 7201, introduced by Representative Rankin (by request), Mississippi, propose to amend 'An Act to maintain the credit of the government of the United States' approved March 20, 1933, to continue retirement pay to certain emergency officers disabled in line of duty during the World War. H R 7135, introduced by Representative James, Michigan, and H R 7204, introduced by Representative Jenkins, Ohio, propose to grant pensions and increases of pensions to certain soldiers, sailors and nurses of the war with Spain, the Philippine insurrection or the China relief expedition and their widows and dependents. The bills apparently make no provision for the pensioning of contract surgeons. Senator Dieterich, Illinois, has proposed an amendment to the Independent Offices Appropriation Bill, H R 6663, to provide that when veterans are eligible for hospital treatment or domiciliary care by reason of neuropsychiatric ailments and who are cared for in state institutions a duty shall devolve on the Administrator of Veterans Affairs to contract with the state or in exceptional cases, with private hospitals, for such medical surgical hospital services and supplies as may be required. Such hospital facilities as may be contracted for under the proposed amendment are to be considered as coming "within the limits of existing veterans' facilities." H R 6906 and 6907 introduced by Representative Smith, Washington, propose to reenact the provisions of laws relating to pensions for Spanish-American War veterans including the Philippine insurrection and the Boxer rebellion, and relating to medical, hospital or domiciliary treatment of former members of the military or naval service that were repealed by 'An Act to maintain the credit of the Government of the United States' approved March 20, 1933. H R 7012, introduced by Representative Kelly, Pennsylvania, proposes to repeal all provisions of 'An Act to maintain the credit of the Government of the United States' approved March 20, 1933, relating to veterans of the Spanish-American War including the Boxer rebellion and the Philippine insurrection. H R 7019 introduced by Representative Disney, Oklahoma, proposes to provide old age pensions for citizens of the United States.

ALASKA

Dr. Council Appointed Health Officer—Dr. Walter W. Council, Juneau, has been appointed health commissioner of the Territory of Alaska to succeed Dr. Harry C. DeVighe. Dr. Council was graduated from the University of Virginia Department of Medicine in 1905 and licensed in Alaska in 1910, first having been licensed in Washington. For several years he was superintendent of the Cordova General Hospital, Cordova, and served as president of the Alaska Territorial Medical Association in 1931.

The Increasing Population of India

The latest census reveals that the population of India now exceeds that of China, which was formerly regarded as the greatest of the countries of the world. The number is 352,837,778, compared with 318,942,480 in 1921 and more than 10,000,000 in excess of that given for China. This increase of 33,895,298 alone approximates the total population of France or Italy. Dr. J. H. Hutton, who was responsible for the 1931 census, regards the increase as a "cause for alarm rather than for satisfaction." Recent writers have stated that India is already living on the verge of scarcity and that any increase will result in an insufficient food supply. Dr. Hutton thinks that recent experience throws doubt on this theory. The general slump in the price of food and the difficulty of cultivators in selling their produce suggest that scarcity of food is not the most serious aspect of the problem. The area covered by the census was more than 1,800,000 square miles, which gives an average density to the square mile of 195. The actual densities vary; one district, Baluchistan, reaching the surprising figure of 4,000. In Europe, the maximum that can be supported by agriculture is 250 persons to the square mile. Generally the maximum density of population can be far greater in India than in Europe, on account of greater fertility of the land and the smaller necessities of life in a less rigorous climate. Though the food products may be ample for many more, a large increase of population must lead either to excessive subdivision of the areas cultivated or to a floating population that has nothing to exchange with the food producers. A definite movement toward birth control appears to be taking place. In 1930 the government of Mysore sanctioned the establishment of birth control clinics in the four principal state hospitals. A curiosity of the census is an aged wrestler, Siddi Wastad, who is supposed to have passed his one hundred and fiftieth year. He was one of the famous wrestlers at the court of the Maharajah Gaiwar, father of the present ruler of Baroda, and saw the last mogul emperor and his predecessor. The census report says "Even allowing for considerable exaggeration, his age would be about 130."

Instinct in the Choice of Foods

Dr. Leslie Harris, director of the Medical Research Council's laboratories at the Institute of Human Nutrition, Cambridge, has investigated the question whether animals select the best foods offered to them. Little precise work has been done in this field. Osborne and Mendel found that rats tended to choose foods containing a better rather than a worse protein. But Beadles and his associates could find no support for the assumption that the more complete of two rations is consumed in greater amount. Some early work of Hoffman indicated that rats would select wholemeal bread at the expense of white bread, but his work was limited in scope by its mainly commercial objective. Certain pediatricians have suggested that on weaning infants should be given a selection of diets and brought up on what they choose and in whatever amount.

Dr. Harris's experimental animal was the intelligent and highly educable albino rat. He chose for the criterion of goodness or 'badness' in a diet the presence or absence of vitamin B as a whole, or the fraction of it known as B₁. Absence of B₁ from the rat's diet even if the diet is complete in all other respects, produces rapid loss of weight and death in from two to four weeks. There were marked signs of nervous disturbance similar to those of beriberi in man.

Equally definite was the result of restoration of the vitamin, provided the animal had not been allowed to become too ill. Dr. Harris found that rats fed on a diet devoid of vitamin B invariably chose a diet containing it in preference to an identical diet without it, provided the complete diet was distinguishable by taste or smell. He next found that, given a choice of several diets deficient in the vitamin and one containing it, rats always chose the latter. This proves that monotony does not put the rat off the best food. In a further series of tests, rats were ingeniously deceived. They were first taught to choose a vitamin-containing diet easily detected by taste and smell. When the vitamin was removed from this diet, without its organoleptic properties being affected, the animals continued to eat it even though the vitamin was incorporated in an alternative diet that previously contained none of it. But after a time the animals went back gradually to the previously rejected diet, now satisfactory, and helped themselves to it exclusively. The animal does not invariably settle down at once to the best diet, though it generally does so. Presumably it makes a number of shots, for the rat is gifted with variable curiosity. If it strikes the good diet quickly it will stick to it, because of the benefits; if it does not, its health will decline and it will go on trying other diets until it strikes the proper one. Dr. Harris argues that this educability of the rat is solely determined by the rapidity with which it recovers from vitamin B deficiency. Unless it experiences benefit it will be unable to choose, and if it does not choose there arises no association of the particular taste and smell of the diet with its curative properties. This explanation is borne out by experiments with vitamin A. On a diet devoid of it the animals may continue in apparently normal health for many weeks, though growth is diminished and resistance to infection lessened. If vitamin A is restored to their diet while they are living on their reserves, they will not notice its effects and therefore when offered a choice of diets with and without vitamin A they make no selection and it appears impossible to educate them to do so.

The Municipal Hospitals of London

The largest hospital service in the world has been administered by the London County Council since 1930. Previously the municipal hospitals were controlled by local authorities or, in the case of the fever hospitals, by a special authority. These hospitals were largely infirmaries for the aged or the disabled and were supported by the municipalities. Their medical staffs were whole time employees without the standing or distinction of the unpaid staffs of the great voluntary hospitals, who are the teachers of the medical schools. Under the new centralized control a great advance has been made in the staffing and equipment of the municipal hospitals. The opportunity for specializing hospitals as much as is desirable has arisen and a part time specialist and consultant staff, drawn from the staffs of the voluntary hospitals, has been appointed. There are at present seventy-four hospitals with a staff, including nurses, approaching 18,500. The annual cost of maintenance is \$22,500,000. The hospitals are under the management of the Central Public Health Committee of the London County Council. In a review of the events covering the period since the transference from local control, the committee says that it is too soon to state that the task of building up a satisfactory municipal hospital service for London is in sight of completion, nor is the task likely to be achieved for some years. But it can be asserted that the transition from diversified control was achieved smoothly, that substantial progress has been made in three years' work with the strengthening of the hospital arrangements in directions in which this was needed, and that administratively the services have been placed on a basis that renders sound development possible.

Special attention has been paid to maternity work, and owing to the popularity of the council's hospitals the tendency is for prospective mothers to seek admission. Live births in the hospitals have increased by more than 2,300 and in 1932 amounted to 10,974, more than one sixth of the total births of London. As an experiment, light anesthesia has been offered in childbirth. Other new measures are (1) reorganization of the observation wards for mental cases, (2) creation of a modern laboratory service, available for all the hospitals, and a complete consultant and specialist service, (3) reorganization of the ambulance and district medical services, and (4) a scheme for the training of nurses.

Typhoid in Paris

The prefect of police issued a bulletin stating that the number of cases of typhoid in Paris at present was above the average, and that it would be a wise precaution to use, for a time, only boiled water for drinking purposes. Dealers in mineral waters took immediate advantage of the announcement to increase their advertising. An inquiry revealed that an accident had occurred in one of the plants supplying drinking water, and that by chance a communication with pipes containing nonpotable water had been established. A double set of pipes is still found in many buildings. There are different faucets for the kinds of water, with precise directions to prevent any confusion. The water termed "potable" is chiefly spring water, which is carefully supervised by the municipal laboratories. But the water system administration, in an emergency, qualifies as drinking water also water pumped from the Seine, filtered in special reservoirs, subjected to sterilization, and then distributed to the urban stations. Such water has a slightly disagreeable taste and is never sufficiently cool in summer. At the same plants, water is pumped from the Seine to be distributed to the pipes containing nonpotable water, used for the cleansing of buildings and the streets. Through an error of a workman, the two systems were brought into communication for a short time, and cases of typhoid developed immediately. The city of Paris is compelled to curtail expenditures for the supplying of spring water. The equipment required for the distribution of spring water represents today a vast sum. Unfortunately the topography of the city increases greatly the difficulties of the water works administration. There are several sections of Paris located on hills (Montmartre, Passy, Le Butte-aux-cailles), with six story buildings. Water pumped from the Seine never attains sufficient pressure to reach these heights, hence it becomes necessary to use solely spring water for all purposes. Nevertheless, typhoid has become rare in Paris, although there are always a few cases. After the war there was a marked decline in the number of cases, owing to the compulsory antityphoid vaccination applied to the mobilized forces and to the nursing personnel, male and female, of the numerous hospitals. Gradually, with the oncoming unvaccinated generations, the number of cases has again increased. There are free vaccination centers in several hospitals, but the public makes no use of them for it has been noised about that vaccination against typhoid may expose a person to considerable discomfort, which is certainly exaggerated. The present menace has however, brought about some activity in these vaccination centers. There are still a few cases of typhoid due to oysters, but these have become more and more rare since the oyster beds have been supervised. However, the baskets of oysters that reach Paris are sometimes contaminated by the retail dealers who to preserve them, leave them secretly in any water that is available whether pure or otherwise.

Administration of Sodium Chloride in Extensive Burns

Research has shown that the blood chlorides are always diminished in case of extensive burns, as was announced by Davidson in 1926. Recent observations by Baur and Boron, army physicians of Nancy, have confirmed this belief, in five persons gravely burned they found the chlorides frankly reduced. Prof. Pierre Duval, in addressing recently the Société de chirurgie, reported some careful observations. The burns of the patient were extensive, seeming, in places, to affect the whole skin. Mr. Duval made studies on azotemia and chloridemia, the urea, the urinary chlorides and the albumoses of the blood. For five days the patient ingested about 15 Gm of salt each day. Examination of the curves revealed the intoxication caused by the burn, and the reaction of the organism. Duval found that the liver transforms into urea the toxic proteins introduced into the blood stream. The defense of the organism is assured by the fixation in the tissues, of blood chlorine, with resulting hypochloridemia and hypochloriduria. He noted also that there is considerable urinary discharge of sodium bicarbonate. It appeared that the sodium chloride of the blood surrenders chlorine to the tissues while the sodium thus liberated unites with the carbon dioxide of the organism and is eliminated as sodium bicarbonate. In this patient the administration of sodium chloride appeared to exert a good effect, for on the seventh day she passed 3 liters of urine with 465 Gm of urea and 1575 Gm of chlorides whereas the elimination on the fifth day had dropped to 200 cc with 295 Gm of urea and 372 Gm of chlorides.

The Weather and Health

The relations between the weather and health, which attracted the attention of Hippocrates, have been the subject of study in France, in recent years. A society was founded recently at Nice, on the initiative of Dr. Maurice Faure, to develop these researches. In a recent communication to the Academy of Medicine, Mouriquand and Charpentier described the symptoms that the wind from the South occasions at Lyons. When this wind blows, all the babies in the Children's Clinic at the Faculté de médecine become restless and cry a great deal. Some show an increase of temperature, others manifest symptoms similar to those of cholera sicca. The explanation is that the winds from the South cause a reduction of the humidity. The extreme dryness of the air is inclined to induce a loss of water, or dehydration. In adults these phenomena produce only slight discomforts but they affect gravely the easily disturbed nutrition of infants, in whom the variations of water balance play a considerable part.

The Increase in Medical Students

Of all the faculties at the German universities the medical faculty shows the most peculiar development. Since the pre-war period, and during the first years following the war, the attendance in the medical department changed more than in any other department. In the last prewar semester (1913-1914) there were about 15,000 medical students or 20 per cent of the total number of university students. After the war there was at first a retrograde movement, the total number of medical students in the winter semester 1924-1925 was about 8,500 or only 14 per cent of the total number of students at the universities. The total number of students in all departments had increased slightly at this time. The increases in the departments of law, political science and chemistry were therefore for the most part, at the expense of medicine. In the winter semester 1927-1928 the attendance of medical students was much greater

and in 1929-1930 the attendance reached 15,650 which exceeded the prewar matriculation.

The figures for the women medical students over this period show an entirely different trend. In the prewar period after women were freely admitted to the study of medicine the attendance was slight, but soon there was a slow but steady upturn. In the winter semester 1913-1914 there were only 870 women medical students at German universities which was but 5.7 per cent of the total number of medical students. In 1927-1928 their number had nearly doubled, and in the winter semester 1929-1930 their number had more than trebled (2,700 women medical students). In this semester the total number of medical students equaled 17 per cent of all students, while the women medical students equaled 17 per cent of the total number of medical students. Since this time the number of men and women medical students has steadily increased. The winter semester 1932-1933 showed a further increase. Whereas, during the period under discussion university attendance in general increased but slowly (from 1929-1930 to 1932-1933 by only about 2 per cent), the medical students presented a different aspect. During this period the latter increased from 15,650 to 24,298, or 55 per cent, and the number of women students rose from 2,718 to 4,913, an increase of about 80 per cent. If one views separately the last comparable period (the winter semester 1931-1932 and the winter semester 1932-1933), the different development of the attendance figures of the medical students in contrast with the students of the other faculties stands out even more prominently. During this period the total university attendance dropped from 95,270 to 92,600, a decline of 3 per cent, at the same time, however, the number of medical students rose from 21,780 to 24,300, an increase of 11 per cent, while the women medical students showed the same trend, with an increase of 15 per cent. These figures show the overcrowding of the medical department. What the future developments will be, under the influence of the new regulations, cannot be foreseen.

Relations Between Diseases of Animals and of Man

The internist Prof. P. Krause of Münster and the hygienist Prof. K. Kisskalt of Munich have published some surprising statements concerning the relations between the diseases of animals and the diseases of man. In connection with outbreaks of epidemic poliomyelitis, for instance, a simultaneous occurrence of disease manifestations in animals has been observed. During the widespread epidemic in Westphalia in 1909, Krause observed, in the district of Arnsberg, a simultaneous increased mortality among young chickens and young blooded dogs. An epidemic-like inflammation of the brain and spinal cord occurs also in colts; it appears likewise in summer and in the fall. It affects chiefly horses in the rural districts, being seldom observed in animals in the city. The disease leads in animals to paralysis of a moderate type.

In this connection, reference may be made to the plague and to Weil's disease (icterus infectiousus) the causative agents of which are the producers of an infectious disease in rats. The causative agent of undulant fever is found normally in goats and sheep, also in cows, horses and dogs, and is transmitted to man by the way of the milk. The conditions are similar in Bang's disease. The causative agent of diphtheria is found also in animals. Hence it is possible that diphtheria is transmitted not only from man to man but also by animals, for example, through the milk, through the appearance of sporadic cases. This actually occurs frequently in diphtheria epidemics. Observations on the migration of diphtheria support this assumption for its passage from one section of the country to another is much slower than would seem likely if it is transmitted by man. It is possible that, with the newer knowledge, some of the mysteries concerning the spread of diphtheria epidemics

can be solved. It has been shown that there are germ carriers among the animals. It is important that, in a disease in which only dissemination from man to man has heretofore been considered, the possibility of transmission from animals to man be recognized. To what extent the number of causative agents of infectious disease occurring solely in man may be further limited cannot be foretold.

Stations for the Collection of Human Milk

A number of years has elapsed since the creation of the first centers for the collection of human milk. In the *Munchener medizinische Wochenschrift*, Frau Dr. Krämer reports on the experiences of the Frauenmilch-Sammelstelle (collection station) in Erfurt during the past six years. The following amounts of milk were dispensed: in 1927-1928, 1,900 liters, 1928-1929, 2,000 liters, 1929-1930, 3,100 liters, 1930-1931, 3,000 liters, 1931-1932, 2,900 liters, 1932-1933, 2,700 liters. The decline in the demand for human milk is doubtless the result of the economic depression in Germany, although it is considerably less than the decline in the consumption of so-called certified cow's milk for infants, during this period. For example, in a good-sized infants' department, at the most 4 or 5 liters of human milk are used, which amounts to from 1,500 to 1,800 liters in a year. The consumers are, for the most part members of the *Frankenkassen*, homes for infants and children's hospitals, the institutions finding it difficult at present to secure wetnurses. The Erfurt collection station procures its supply of milk from about fifty women during the course of the year. Their average compensation ranges from 30 to 40 marks per month, which, in many cases, constitutes an important addition to the family income. The milk is sterilized for fifteen minutes in 200 Gm flasks. After the lapse of two months, the milk has been found to be still satisfactory from the standpoint of bacterial content. No marked reduction of vitamins occurs.

MADRID

(From Our Regular Correspondent)

Nov. 29, 1933

International Congress on Cancer

The International Congress on Cancer was held October 25-30, at Madrid under the presidency of Dr. Leon Cardenal, professor of surgery of the Faculty of Medicine of Madrid. The president of the republic welcomed those who attended. There were receptions at the national palace and the city hall, banquets, bull fights and dances. The following official topics were discussed in the scientific section, biology of the cancer cell, early diagnosis of cancer, and treatment of cancer and tumors of the nervous system. In the professional section, occupational cancer, cancer of the races and prevention of cancer. Besides the official topics, more than 450 articles were presented before the more than a thousand persons who attended the congress. Drs. Ewing, Grant and Gendreau represented the government of the United States. Drs. R. S. Ferguson and J. D. Humber of the United States read papers on Intermedin in the treatment of melanoma and research on the cause and treatment of cancer, respectively. Several other American physicians read papers. There were 24 members from the United States, 40 from Germany, 74 from France, 26 from Switzerland, 18 from England, 12 from Austria, 20 from Belgium, 20 from Argentina, 26 from Italy and 6 from Russia.

SCIENTIFIC SECTION

The first topic, "Biology of the Cancer Cell," was discussed by Dr. J. A. Murray of London. The essential nature of cancer remains unknown. Carcinogenic agents applied in a uniform manner to an extensive area result in cancer only in localized areas. Chemical and physical carcinogenic agents act indirectly by determining in the tissues certain conditions which

serve as the starting point for the development of cancerous lesions. It has not been shown from the chemical constitution of those agents how the autonomous type of cellular proliferation takes place. Perhaps the tissues set free substances of more or less chemical similarity to some of the known carcinogenic compounds.

Dr. Gurwitsch of Leningrad spoke on "Stimulation of Cellular Division." A piece of tissue in a proper environment is capable of stimulating proliferation in other cellular complexes when the latter are exposed to the influence of the former. That is what happens, even at a distance. The cornea of rats and frogs placed a few millimeters from a tumor recently removed and triturated, shows more mitosis after a certain time than does the cornea of an eye not thus subjected to the influence of the tumor. The same happens when other tissues, tissue cultures or bacteria are exposed to the influence of the tumor material. The number of cells in the exposed culture is 30, 50 and even 100 per cent greater than that in the control culture. These results prove that the tumor is capable of acting on the cells even at a distance. This action, however, is not an exclusive property of cancer tissue. Any aggregation of proliferating cells has in the element of quartz the carrier of an agent capable of stimulating at a distance the division of cells of other cellular aggregations. This agent is not specific. It is transmissible through quartz and is of the nature of ultraviolet rays of wavelengths between 1,900 and 2,500 angstrom units. This has been proved both by spectrum analysis and by a physical method based on Geiger-Mueller's principle. The first method is simple. Between a tumor and a yeast culture there is interposed a quartz spectrograph provided with a horizontal slit which has a scale of wavelengths instead of a photographic plate. The tumor is placed in front of the slit of the spectrograph. A series of cultures of yeast is placed in front of the different divisions on the spectrograph scale. Stimulation occurs at some wavelengths but not at others. The sensitivity of the cells for ultraviolet rays is of the same order as that of the retina for light rays. The most varied chemical reactions especially those of a fermentative nature (oxidation, peptic processes, the actions of phosphatase, amylase and urease, as well as more simple reactions, such as the neutralization of an acid by a base and even certain processes of dissolution) are sources of ultraviolet radiations, also called mitogenic radiations because of their property of provoking mitosis. It may be supposed that emission of ultraviolet rays occurs as a result of many chemical reactions. Not all the tissues in the body emit mitogenic rays. These can be detected only from the blood, nerves, muscles and mucous membranes of the small intestine. It is necessary that the cells be in a proper condition to react to the stimuli. The Hammetts have proved that the sulphhydryl (SH) group which is a constituent of protoplasm, stimulates cellular proliferation. These authors believe that the role of sulphhydryl in the production of mitosis is proved. The speaker believes that the mitogenic rays are of the same order of activity as sulphhydryl. Can an explanation of carcinomatous proliferation be found in mitogenic irradiation? Experiments have proved that those radiations have not only an influence on the division of the cells but also an accelerative action on the rhythm of mitosis. Not only the beginning of mitosis but its entire course as well proceeds under a mitogenic influence. Secondary irradiation is found in most tissues and in different chemical solutions, which acquire them after having been subjected to the mitogenic rays. It is sufficient to irradiate one end of an aggregation of cells to convert the whole aggregation into a source of secondary radiation. There seem to be two groups of cells in the cultures: one which reacts to the irradiation by an early division and the other, which, having been deprived of the power of multiplication, reacts with the development of a secondary irradiation. Tumors do not lose

their properties of radiation, while the blood of any individual ceases to emit radiations after six or seven hours. The blood of cancer patients does not emit radiations and this is one of the earlier signs of the presence of neoplasms. An eye recently removed from the body and kept in physiologic dextrose solution does not show traces of radiation, while a tumor continues its radiation without diminution in nature or intensity for a long time. The radiation emitted from the cornea appears to represent a secondary phenomenon, probably originating in the blood. Attention has been called to the increased permeability of the cancer cell. It is easy to demonstrate that the intracellular ferments of the cancer cells traverse the cell membranes with ease. If a tumor is kept for thirty minutes in Ringer's solution, the solution acquires the tumor ferments, the presence of which can be proved by the spectral analysis of the mitogenic radiations of the solution. Similar experiments on normal organs instead of tumors give negative results. This is of importance, since those ferments appear to be the source of intense mitogenic radiations. The cancer cells, besides being the origin of radiations, are surrounded by a mitogenic environment, which further increases the permeability of the cell. That is, the mitogenic influences of carcinoma play an important part in the mechanism of proliferation of carcinomatous cells.

Dr Berst of Munich, who spoke on "Histologic Diagnosis of Malignancy," said that the destruction of cells and the formation of metastases are the most certain signs of the malignant character of a tumor. There is no morphologic specificity of the malignant cell. The presence of atypical nuclei and mitosis and of a nuclear variability are important. The stroma of the tumor is less important in the histologic concept of malignancy.

Dr A. Fischer of Copenhagen said that until recently the study of cancer was in the same condition that the study of infections was before the bacterial era. At present by the determination of the respiratory metabolism of the cancer tissues and also by the technic of tissue culture, the physiology of cancer cells can be studied. It has not been proved that there are many qualitative differences between the normal and malignant cells. The cancer cell differs from the normal cell only quantitatively in regard to the power of glycolysis and proteolysis and in its capacity to build new protoplasm with the plasma of the blood as the only source of nutrition. The mechanism of the unlimited development of tumor cells is at present clearly understood. This knowledge is based on the comparative estimation of the growth of normal and of pathologic tissue and also on experiments with cultures of both types of tissue. In tissue cultures the interaction between the normal and cancer cells can be studied. It consists in a mutual stimulation, a reaction of the stroma, infiltration and destruction. The development of cells of tissues is considerably accelerated by subjecting the culture to repeated slight injuries. Tumor cells are less resistant than normal cells to any form of injury, and the duration of their life is short. Malignant tissue cells are continuously being killed in the cultures. This fact explains why more mitosis is observed in cultures of cells of carcinoma than in cultures of normal cells in spite of the fact that the latter grow apparently faster than the former. The conclusion can be drawn that the unlimited proliferation of tumor cells in the body is the physiologic result of the spontaneous death of the cells in the same manner in which the normal regeneration is provoked by the injury to the cell.

Dr Sanchez Covisa of Madrid spoke on precancerous lesions which he divided into two groups. The first group includes certain diseases that often become cancerous spontaneously, such as xeroderma pigmentosum, Paget's disease and Bowen's disease. It has been proved that some diseases in this group are really tumoral processes. The second group includes those lesions which may become cancerous under certain circumstances

and in the development of which physical, chemical and parasitic agents may have had an influence. In this group are lesions caused by either solar or roentgen radiations, as well as cancer developed from scars, and arsenical cancer. The speaker stated that although there is a group of lesions which precede the appearance of cancer, it cannot be said that a definite group of precancerous diseases exists. One cannot speak of a precancerous cell, nor can it be stated in all cases whether the cancerous cell was cancerous from its beginning or is the result of the transformation of a normal cell. In order that a malignant process may arise, a local cellular alteration is necessary and also a general disequilibrium, manifested in metabolic changes that characterize the cancerous 'terrain'.

Dr Keyser of Berlin exhibited a collection of photographs showing the results obtainable with electrosurgery in the treatment of cancer, especially in circumscribed cases, even those which appear to be inoperable.

Drs Roussy and Leroux of Paris commended the biopsy in the diagnosis of cancer and displayed a cinematographic film showing various techniques.

Dr Fischer of Wasel in Frankfurt has experimentally proved the significance of a general predisposition for the development of cancer. The fundamental disturbances that are described as the originators of the predisposition are (1) increased fermentation (glycolysis) and limited respiration, (2) alkalosis of the blood and (3) inhibition of the functions of defense in the reticulo endothelial system. The speaker made reference to methods by which the general predisposition to cancer may be overcome.

Drs Schinz of Zurich, Wintz of Erlangen, Holthusen of Hamburg, Rodriguez Lopez of Santa Cruz de Tenerife and Vicente Carulla of Barcelona spoke on roentgen therapy given in fractional doses in the treatment of cancer. These papers, rich in detail, were of great value. Dr Rodriguez Lopez concluded that in the roentgen treatment of cancer the fractional method has the following advantages over the unisessional method. More roentgen energy, about three times as much, is accumulated in the latent cells, it stimulates the cells to proliferation and consequently to become more sensitive to radiation, and it attacks the cells during their most sensitive period, that is, during the period of nuclear division, and by so doing kills a large number of cells.

SOCIAL SECTION

Dr Luigi Carozzi of Geneva spoke on occupational cancer, the prevention of which should be based on the determination of the cause and the avoidance of contact of workers with toxic products. Workers should be examined either when they start working or at intervals in order to ban those who because of their constitution, may easily become victims of cutaneous cancer, and also in order to make an early diagnosis of precancerous lesions. It is desirable that research on occupational cancer be continued in order to study the causes, especially in those cases which develop under the influence of agents causing chronic irritation.

Dr James Ewing of New York spoke on the prevention of cancer. The campaign against cancer has made progress in the diagnosis and treatment of early cases but not in advanced cases. There is no reasonable basis to expect that any cure can be discovered in the near future which can alter the conditions which at present exist in relation to cancer. The prevention of cancer requires a wide knowledge of the stimulative factors and conditions that bring about cancer. The importance of this problem deserves much more attention than has been given it. Certain forms of cancer (skin, uterus, mouth) are preventable. Certain other forms such as cancer of the gastrointestinal tract can be alleviated by improving the diet, leading a moderate life and improving the general hygiene. One

should teach the average person the prevention of cancer and the practice of temperate and moderate habits. One should enforce the protection of workers in cancerogenic industries. Those agents that are related to the origin of cancer should receive publicity. In spite of campaigns to teach laymen on this subject, physicians cannot be optimistic about the results. Cancer phobia is a necessary phobia in any civilized person.

Dr. Maisin of Louvain spoke on legislation on cancer. He presented the following outline:

I. Contact should be avoided with cancerogenic agents that may injure by contact, ingestion or inhalation.

1. This can be done by:

- (a) Demanding strict hygiene from the workers.
- (b) Removing from the industrial equipment the active cancerogenic tar.
- (c) Prohibiting the use of cancerogenic oils for lubrication.
- (d) Removing toxic hydrocarbons liberated in the combustion of carbon and doing the same with heavy oils.

2. The use of radioactive substances should be declared dangerous.

- (a) The ingestion and the injection of any radioactive agent ought to be prohibited.

3. It is necessary to study the toxicity of stains.

II. It is necessary to suppress parasitism, all foci of chronic infection, syphilis and tuberculosis, since they play an indirect role in carcinogenesis.

III. Trauma may provoke the development of cancer if the individual is predisposed to the disease. There is a certain relation between trauma and cancer.

IV. Cancerogenic substances may be present in some foods and cause cancer a long time after they are ingested. The use in food of artificial agents, such as dyes and stains, should be prohibited until their harmlessness from the cancerogenic point of view has been proved.

The speaker said that there are either favorable or injurious diets for cancerous patients. Mineral substances can have either favorable or injurious effects on the development of cancer. Potassium favors the development of cancer while calcium and magnesium retard it.

Dr. Paulina Luisi of Montevideo, Uruguay, read an extensive exposition on the organization of a crusade against cancer. She said that a center for the cancer campaign should be provided with all the units required by its various aims. There should be units for the prevention of cancer (its investigation, detection and early diagnosis), for treatment for the care of patients in hospitals and in homes and for educating laymen about scientific discoveries, and there should be units for cooperating with other campaigns (international union).

Dr. Pittaluga of Madrid reported on the work done in Spain in the crusade against cancer. The organization published seventy-five articles on cancer from 1923 to 1927. Since 1928 the members of the committee have centered their efforts on the study of roentgen therapy of cervical cancer and on the investigation of occupational cancer.

Dr. Gallenga of Rome discussed instructions for the general practitioner in a crusade against cancer.

Dr. Prochazka of Prague presented a general outline for the education of laymen on matters related to cancer.

Cholesterol and Cancer of the Skin

Dr. A. H. Roffo of Buenos Aires recently lectured in the Academia Nacional de Medicina of Madrid on the role of cholesterol deposits in the skin in the development of cutaneous cancer. He said that the amount of cholesterol in the skin is in inverse proportion to the amount of exposure of the skin

to the sun's rays. In those areas of the skin which are not exposed to sunlight, such as the skin of the abdomen, there is the minimum amount of cholesterol; there is several times as much in the skin of the areas exposed to the sunlight, such as the forehead, the alar nasi and the cheeks. Cholesterol deposited in the skin in the form of the classic yellow spots well known to cancerologists, becomes active under the influence of sunlight and provokes the multiplication and cancerous proliferation of the cells that are immediately near it. Dr. Roffo presented abundant data and a large number of photomicrographs. The number of cases reported by the speaker was large.

Patient Expires During Operation at International Congress

The failures of operations performed during international congresses are rather frequent. The immediate results of the operation sometimes seem wonderful but hours later the family physician has been summoned in haste to find that the patient has died. The cause of these tragedies seems to be related to conditions under which the surgeons operate. They perform an operation on patients not previously known or carefully examined by them and in a strange environment. They are living during the days of the congress differently than they do at home. During one congress a well known surgeon operated to close a fissure in the vault of the palate before a large audience. The operation soon had to be discontinued because the child died from syncope. The surgeon experienced such a terrible shock that it greatly affected his personality. Other tragedies of the same sort have occurred. During the International Congress on Cancer, a famous surgeon performed an operation with the electric knife on a woman who had an extensive tumor of the breast. His instrument entered the thoracic cavity, some say it even reached the myocardium. The patient became weaker and weaker and the operation was finally discontinued, when a Spanish surgeon who was acting as assistant told the visiting surgeon that the patient was dead. All the medical attendants present were with terror, the unfortunate patient expired.

Prize for an Article on Cancer

The late Dr. Recasens devoted his life to the crusade against cancer. He died a victim of cancer. His widow recently founded a prize which represents the interest on \$50,000 for the best article on cancer to be presented in the near future.

Marriages

EDWARD PORCHER BRUNSON, Albemarle, N. C., to Miss Charlotte Wilson Miles of Danville, Va., Dec. 13, 1933.

MARVIN LONGWORTH SLATE, High Point, N. C., to Miss Marion Wolfersberger of Baltimore, Dec. 23, 1933.

WALTER LEE O'NEAL, Henderson, Ky., to Miss Bernice James of Lebanon, Ohio, at Cincinnati, January 12.

JOSEPH PHILIP SKLOCH, Arkadia, Wis., to Miss Mabel Gillons of Grand Rapids, Mich., Dec. 23, 1933.

NATHAN JUDSON BENDER, Poteet, Texas, to Miss Lorelle Causey of Franklinton, La., Dec. 27, 1933.

PAUL ROYSTON SCALLIN, Clark, S. D., to Miss Louise R. Wiggins of Flint, Mich., recently.

FENWICK BELLMAN, New York, to Mrs. Vera Byerley at Greenwich, Conn., Dec. 8, 1933.

DENNIS WHEELER SWEENEY to DR. HILLEN H. OWEN, both of New York, January 6.

ROY ALVIN SCHWACHE, McGregor, Minn., to Miss Viola Cayo of Tamarack, recently.

G. M. GRAHAM STAFFORD, Alexandria, La., to Miss Dorothy Schulze, Dec. 28, 1933.

GRAHAM L. BENNETT to DR. MOSETTA C. WHITE, both of New York, January 1.

Deaths

Joseph Edward Root, Hartford, Conn. College of Physicians and Surgeons, Medical Department of Columbia College New York, 1883, member of the Connecticut State Medical Society, fellow of the American College of Surgeons, orthopedic surgeon to St Francis Hospital, consulting orthopedic surgeon to the Manchester Memorial Hospital, South Manchester, Newington (Conn.) Home for Crippled Children, Municipal Hospital, Hartford and the Shriners Hospital for Crippled Children, Springfield, Mass., aged 79, died, Dec 18, 1933, of cerebral thrombosis

Earl Dean Crutchfield San Antonio, Texas, University of Texas School of Medicine, Galveston, 1918 member of the American Dermatological Association and the Radiological Society of North America, fellow of the American College of Physicians, formerly professor of dermatology and syphilology at his alma mater, on the staffs of the Robert B Green Memorial Hospital and the Santa Rosa Infirmary, aged 43, died, Nov 30, 1933 following a staphylococcal septicemia

Joshua Clapp Hubbard, Wayland, Mass. Harvard University Medical School, Boston 1896 member of the Massachusetts Medical Society, American Surgical Association and the New England Surgical Society, formerly clinical professor of surgery at his alma mater, served during the World War, at one time on the staff of the Boston City and Boston Lying-In hospitals, aged 64, died, January 11

Zebulon Vance Sherrill, Marion Va. University of Louisville (Ky.) School of Medicine, 1888, member of the Medical Society of Virginia, past president of the Smyth County Medical Society, now known as the Southwestern Virginia Medical Association of which he was also president aged 71, died, Dec 11, 1933, in St Elizabeth's Hospital, Richmond, of rectovesical fistula and peritonitis

Walter Sands Mills, Brooklyn New York Homeopathic Medical College and Hospital, 1889, associate professor of medicine at his alma mater, served during the World War author of "Practice of Medicine", aged 68, on the staff of the Metropolitan Hospital, Fifth Avenue Hospital and the Flower Hospital, where he died, January 5, of chronic myocarditis

James Gustavus Eblen, Lenoir City, Tenn., Southern Medical College, Atlanta, 1898, member of the Tennessee State Medical Association, past president and secretary of the Loudon County Medical Society formerly mayor, member of the board of education and board of health, aged 65, died, January 1, in the Fort Sanders Hospital, Knoxville, of sprue

Walter Spaulding Mix Beardstown, Ill. University of Illinois College of Medicine, Chicago, 1915, member of the Colorado State Medical Society, served during the World War, formerly on the staff of the Agnes Memorial Sanatorium, Denver, aged 42, died January 6 in Virginia Ill, of pulmonary tuberculosis

William Nevin Adkins, Atlanta Ga., Atlanta College of Physicians and Surgeons, 1905 member of the Medical Association of Georgia, served during the World War county health officer on the staffs of the Grady and Georgia hospitals, aged 50, died, January 5, in a local hospital, of cirrhosis of the liver

Eli Grimes Des Moines, Iowa State University of Iowa College of Medicine, Iowa City 1897 formerly professor of clinical medicine Drake University College of Medicine, aged 66 on the staff of the Iowa Lutheran Hospital, where he died January 14, of carcinoma of the pancreas

George Smith Condit Warren Pa. University of Maryland School of Medicine, Baltimore, 1910 member of the Radiological Society of North America served during the World War, on the staff of the Warren General Hospital, aged 46, died Dec 10 1933 of bronchiectasis

Alexander Blake MacNab Cassopolis, Mich. Rush Medical College, Chicago, 1907 past president of the Cass County Medical Society, served during the World War aged 54 one of the owners of the McCutcheon Hospital where he died Dec 10 1933, of bronchopneumonia

James J Morony Breese Ill. Marion Sims College of Medicine, St Louis 1895, past president of the Clinton County Medical Society for many years county coroner aged 68 on the staff of St Joseph Hospital where he died January 4 of arteriosclerosis and secondary anemia

George Young Moore Cuthbert, Ga. University of Georgia Medical Department Augusta 1888 past president of

the Medical Association of Georgia, secretary of the Randolph County Medical Society, aged 65 died, Dec 24 1933, of cerebral hemorrhage and coronary disease

Edwin Forrest Bickel Oshkosh, Wis. Medico-Chirurgical College of Philadelphia, 1903, formerly member of the school board, served during the World War, aged 55, on the staff of the Mercy Hospital, where he died, January 10, of carcinoma of the transverse colon

Raymond Kiesling Derr, Pennsburg, Pa., Jefferson Medical College of Philadelphia, 1927, member of the Medical Society of the State of Pennsylvania, on the staff of the Quakertown (Pa.) Hospital, aged 36, died, Dec 25, 1933 in the Jefferson Hospital, Philadelphia

Charles Walker Stewart, Washington, Iowa, Rush Medical College, Chicago, 1891, member of the Iowa State Medical Society, health officer, formerly on the staff of the Washington County Hospital, aged 68, died, Nov 12, 1933, of traumatic ileus

Thomas Emilo Snoddy, Russellville, Ala., Emory University School of Medicine, Atlanta, Ga., 1925, member of the Medical Association of the State of Alabama, aged 32, died, January 5, in the Baptist Hospital, Memphis, Tenn., of pneumonia

Guy Scofield Shugert, Rochester Pa., Western Pennsylvania Medical College, Pittsburgh, 1897 member of the Medical Society of the State of Pennsylvania, on the staff of the Rochester General Hospital, aged 57, died, Oct 5, 1933, of myelitis

Ernest M H Highfield Alma, Mich., Detroit College of Medicine 1904, past president of the Gratiot-Isabella Clare County Medical Society, on the staff of the Carney-Wilcox Hospital aged 56 was found dead, Dec 29, 1933, of heart disease

Charles A C Parker, Dongola, Ill., Marion-Sims College of Medicine, St Louis 1892, member of the Illinois State Medical Society, formerly member of the school board and mayor of Dongola aged 70, died, Nov 26, 1933

Lee Roy Salmons Winston-Salem, N C., North Carolina Medical College, Charlotte, 1912 served during the World War, on the staff of the Winston-Salem Hospital, aged 43 died, January 9, of acute dilatation of the heart

Elmer Ellsworth Shannon, Ivoryton, Conn., Cleveland Homeopathic Medical College, 1898, Hahnemann Medical College and Hospital of Philadelphia, 1900, aged 57, died, Dec 4, 1933, of arteriosclerosis and chronic myocarditis

Jacob Markwood Peters, Camp Hill, Pa., Jefferson Medical College of Philadelphia, 1886, member of the Medical Society of the State of Pennsylvania, aged 71, died, Nov 15, 1933, of coronary embolism and arteriosclerosis

Le Roy Vincent Reilly, Morristown, N J., Georgetown University School of Medicine Washington D C 1933 intern at the All Souls Hospital, aged 26, was found dead Dec 21 1933 as the result of an automobile accident

George Rochefoucauld Plummer Key West, Fla. Southern Medical College Atlanta Ga., 1893, past president of the Monroe County Medical Society, served during the World War, aged 62, died Dec 31, 1933

Augustus Edwin Smith, Warren, Ohio, Jefferson Medical College of Philadelphia, 1911 member of the Ohio State Medical Association on the staff of St Joseph's Hospital, aged 53, died, January 4, of heart disease

Francis Edwin Corey, Alhambra, Calif., University of Michigan Medical School, Ann Arbor, 1868, formerly health officer of Alhambra aged 87, died Dec 2 1933, of arteriosclerosis and cerebral hemorrhage

Luther H Clark, Kyle, W Va., College of Physicians and Surgeons Baltimore, 1892, superintendent of the Welch (W Va.) Emergency Hospital, aged 63, died suddenly, Dec 23, 1933, of cerebral hemorrhage

John Wesley Mosser, McConnellsburg, Pa., Medico-Chirurgical College of Philadelphia, 1899, member of the Medical Society of the State of Pennsylvania, aged 66, died, Oct 13, 1933, of heart disease

Robert Lee Raby, Gatesville, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1891, member of the city council, formerly city and county health officer, aged 65, died Nov 19 1933

Arthur William Hubbard Wyoming N Y, University of Buffalo School of Medicine, 1887 health officer of the consolidated health district of Middlebury-Wyoming aged 69 died, Nov 23 1933

Asa F Goodwin, Louellen, Ky Kentucky School of Medicine, Louisville, 1902, member of the Kentucky State Medical Association, aged 55, died suddenly, Dec 25, 1933, of cerebral hemorrhage

Charles Louis Swan, Stoughton Mass Harvard University Medical School, Boston, 1894 for three years member of the school committee, aged 66, died suddenly Dec 31, 1933, of heart disease

Charles Alonzo Shoemaker, Lincoln Neb University of Nebraska College of Medicine Homeopathic Department, Lincoln, 1886, for many years county coroner, aged 72 died, Nov 29, 1933

Earl Eugene Heath, Advance, Ind Ohio Miami Medical College of the University of Cincinnati, 1910 served during the World War, aged 53, died, January 2, of a self inflicted bullet wound

Everett Henry Butterfield, Milwaukee Rush Medical College, Chicago, 1884 served during the World War aged 71 died, January 2, of hypertension and hypertrophic cirrhosis of the liver

James Elmo Mayne Winchester Mass University of Toronto Faculty of Medicine, 1926 aged 32 on the staff of the Winchester Hospital, where he died, Dec 26 1933, of pneumonia

Frank W Hayden, Pawtucket, R I Baltimore Medical College, 1901, member of the Rhode Island Medical Society aged 61, died, Nov 18, 1933, of lobar pneumonia and heart disease

Paul Richard Hess Reading, Pa, Jefferson Medical College of Philadelphia, 1929, aged 32 died, January 8 in St Joseph's Hospital, of a gunshot wound inflicted by a patient

James W Kincaid Catlettsburg Ky Medical College of Ohio, Cincinnati, 1880, past president of the Kentucky State Medical Association, aged 74, died, Dec 20 1933, of heart disease

Henry Allen King, New Iberia La Tulane University of Louisiana Medical Department, New Orleans 1889 member of the Louisiana State Medical Society aged 67 died Dec 8 1933

Claude Brantley Brookins, Gordon Ga University of Georgia Medical Department, Augusta 1912 served during the World War, aged 47, died recently of angina pectoris

Charles Burdick Cunningham, Warrensburg N Y Albany (N Y) Medical College, 1888 past president of the board of education, aged 73, died, Dec 17, 1933, of pneumonia

John Sherman Darnell, Talking Rock Ga Georgia College of Eclectic Medicine and Surgery, Atlanta 1893 aged 69 died, Oct 26, 1933, of chronic nephritis and cardiac hypertrophy

Judge Corey Kirkpatrick, Roll, Ind Indiana Medical College, School of Medicine of Purdue University Indianapolis 1907 aged 66, died suddenly, January 2 of heart disease

Rufus Maurice Musick, Delbarton, W Va, Eclectic Medical College, Cincinnati, 1916 served during the World War, aged 43, died, in December, 1933 of acute nephritis

George Johnson Rittenhouse, Glendale Calif College of Physicians and Surgeons Medical Department of Columbia College, New York, 1894, aged 60, died Nov 12 1933

Irving Culver Barnes Indianapolis Indiana Medical College, School of Medicine of Purdue University Indianapolis 1906, aged 49, died suddenly, January 8 of heart disease

Robert S Pardue, Riverside, Calif University of Louisville (Ky) School of Medicine, 1888 aged 77 died Nov 19 1933, of bronchopneumonia myocarditis and nephritis

John Tarleton Scollard Milwaukee Rush Medical College, Chicago, 1887, aged 77 died suddenly January 9 in the Columbia Hospital, of chronic nephritis and uremia

Scott Wolford Lau Philadelphia Jefferson Medical College of Philadelphia, 1899, aged 59 died Dec 17 1933, of heart disease at North Wildwood N J

J Francis Dunlap Manheim Pa, Jefferson Medical College of Philadelphia, 1875, aged 80, died, Dec 12 1933 of chronic myocarditis and angina pectoris

Jacob Tobias Pollock, Chelsea, Mass College of Physicians and Surgeons, Boston, 1913, aged 44 died Dec 28 1933, of tuberculosis of the kidneys and bladder

Ernest Spencer Case, Inglewood Calif Omaha Medical College, 1895, formerly member of the state legislature in Nebraska, aged 61 died Nov 25 1933

William Thompson Talbott Calexico, Calif, College of Physicians and Surgeons, Los Angeles, 1918, health officer of Calexico, aged 52, died, Nov 9, 1933

Charles W Hendrickson, Amherst Neb, Ensworth Medical College, St Joseph, 1908, aged 47, died, Nov 21, 1933, of angina pectoris and arteriosclerosis

John H McKibbin, Los Angeles Medical College of Indiana, Indianapolis, 1887 aged 85, died, Dec 19, 1933, of chronic myocarditis and nephritis

George Raymond Wells Monroe Ga, Atlanta Medical College 1892, on the staff of the Walton County Hospital aged 65 died, Nov 26, 1933

William Hutchinson Morse, Seattle, Medizinische Fakultät der Universität Leipzig Leipzig, Saxony, Germany, 1901, aged 59, died Dec 21, 1933

John Henry Groshans, Baltimore, University of Maryland School of Medicine Baltimore, 1894, aged 63, was found dead, January 2, of heart disease

William James Garbutt, Milwaukee (licensed, Wisconsin 1900), aged 86, died, Dec 11, 1933, of gangrene of the lower limbs and arteriosclerosis

Charles Andrew S Sims, Kansas City Mo, St Joseph Hospital Medical College 1882, aged 72, died, Nov 13, 1933 in Long Beach Calif

Wilberforce Clarkson Doy, Boston, Homeopathic Hospital College, Cleveland, 1872, aged 82 died, January 3 of chronic myocarditis

Frederick Boyd Tapley, Marysville Calif Hahnemann Medical College of the Pacific San Francisco, 1906, aged 50, died Nov 27 1933

Cyrus R Cox, Lynn, Ind Medical College of Indiana Indianapolis 1878 aged 80, died, January 6, of myocarditis and arteriosclerosis

Montague J Lowry Meridian Miss Hospital College of Medicine, Louisville, 1879, aged 76 died, Dec 20 1933 of heart disease

Lucy Barney Hall Church, Dedham Mass, Boston University School of Medicine 1893 aged 67, died Dec 28, 1933, of heart disease

Emma Virginia Boone, Philadelphia Woman's Medical College of Pennsylvania, Philadelphia, 1880, aged 72, died, Nov 12, 1933

Orrin Dayton Kingsley, Rochester, N Y New York Homeopathic Medical College, New York, 1874, aged 84, died Dec 9, 1933

John F Dismukes Milton, Tenn University of Georgia Medical Department, Augusta 1889, aged 81, died suddenly, Dec 1, 1933

Ross H Shepler, Green City, Mo, Keokuk (Iowa) Medical College 1898 aged 63 died Dec 16 1933, in a hospital at Kirksville

John Logan Reynolds, Blackford Ky Kentucky School of Medicine Louisville 1898, aged 71, died Dec 20, 1933, of tuberculosis

Richard J Kenna Brooklyn Baltimore University School of Medicine 1901 aged 55 died, Dec 30, 1933, of cancer of the liver

William Bond Winkler, Fort Myers, Fla, Memphis (Tenn) Hospital Medical College, 1881 aged 76, died, Oct 31 1933

John Scott McBride Seattle Detroit College of Medicine, 1897, city health commissioner aged 59, died, Nov 15, 1933

Thomas Cooper Wilson, Glen Ridge, N J, Jefferson Medical College of Philadelphia 1895, aged 63 died, Nov 18 1933

Michael Nolan, Haverhill Mass, Vermont Medical College Rutland, 1889, also a druggist, aged 81, died, Nov 19, 1933

William Franklin Miranda, Walkerton Ind, Medical College of Ohio Cincinnati, 1877 aged 82, died Dec 24, 1933

Oscar John Carlin, Pottsville Pa, Medico-Chirurgical College of Philadelphia 1901 aged 57, died, Dec 31, 1933

Alcinous Smyth, Kingsville Texas, Chaddock School of Medicine, Quincy Ill, 1884 aged 82, died Nov 23, 1933

Samuel Madison Watson, Alton Ill (licensed, Illinois 1883) aged 88 died Nov 24 1933 of hepatic carcinoma

Samuel S Korngut, Elizabeth N J New York University Medical College 1898 aged 62 died Dec 4, 1933

ABORTION OR FETICIDE VS HOMICIDE

To the Editor—I thank you for your fair review of my book "The Law Against Abortion" (THE JOURNAL, January 6, p 71). You have let me off rather easily. Of course, I did not expect the reviewer of THE JOURNAL to agree with my views. There are some points, however, in the review on which I should like to be permitted to offer some comments.

Your reviewer places feticide, infanticide and homicide on exactly the same level. "Why he would tolerate feticide and forbid infanticide and other forms of homicide is not apparent," he writes. May I remind your readers that when I initiated the propaganda for birth control thirty years ago, the same thing exactly was said about the prevention of conception that is now being said about abortion. Many physicians at that time and some physicians even now place prevention on exactly the same level as murder. Perhaps in twenty-five years from now the views on abortion in certain cases will also undergo a radical change.

Your reviewer states that he is in doubt whether my book is intended for the medical or the lay reader. If one wishes certain reforms to be brought about, one must appeal to the laity. During the first years of my birth control propaganda, I appealed to the profession exclusively. The response until I succeeded in converting Dr. Abraham Jacobi to the importance of birth control, was slow. Had the birth control propaganda been limited to the profession alone, the movement would not be as far advanced as it is now. And if a modification of the abortion law is desired, it is necessary to enlist the cooperation of the intelligent laity.

Your reviewer writes, "Laws forbidding the inducing of abortion have not interfered, so far as is known, with the inducing of a therapeutic abortion to save the life of any woman whose life has been endangered by pregnancy, nor are they likely to do so." That is true, and I quite agree with your reviewer. But I claim that there are conditions in which pregnancy is as great a calamity and if unreheved may have as disastrous consequences as are apt to follow tuberculosis, nephritis or acute cardiac disease.

WILLIAM J. ROBINSON, M.D. New York

LOCAL APPLICATION OF HEAT AND COLD

To the Editor—In the editorial on the internal temperature of the body (THE JOURNAL Dec 2, 1933, p 1805) dealing with the studies of Hepburn and his collaborators of Philadelphia, the interesting observation is recorded that the application of heat or cold to the skin does not cause any alteration in the temperature of the corresponding part of the intestine and it is concluded therefore that the production of any reparative benefit by local application of heat or cold is conjectural. While the observation is no doubt correct, the conclusion seems unwarranted. There are effective segmental nervous connections between the skin and the viscera. Wernicke showed that a disease condition of the viscera will give rise not only to hyperesthetic zones in the skin but to changes in vascularization which can be objectively demonstrated and in experiments on fishes in my laboratory he demonstrated the existence both of sympathetic axon reflex paths between the skin and the viscera and of true spinal reflexes. In a segment of the eel with an intact spinal cord strong stimulation of the skin will cause hyperemia of the corresponding part of the intestine, while after destruction of the spinal cord the same stimulus will cause ischemia through the axon reflex path. In

human beings, Ruhmann inserted a laparoscope through a small incision and directly observed that the application of heat (46 C) to the skin of the abdomen brought about after four to six seconds latency a reflex hyperemia of the corresponding part of the intestine. There can be little doubt that this reaction is responsible for the benefit observed in a number of cases after application of thermal stimulation to the skin, even though the increased blood flow in the case of an internal organ cannot produce any rise in temperature.

The reflex mechanisms concerned are discussed and the literature is cited in my book "The Anatomy and Physiology of Capillaries," lecture VII, Yale University Press, 1929.

AUGUST KROGH, Copenhagen

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

ARTIFICIAL IMPREGNATION

To the Editor—I am desirous of receiving information concerning the most frequently used and most successful method of artificial impregnation which I have been asked to administer by a patient with the following history: A woman, aged 37 years, in good physical condition had her first pregnancy in 1924. The pregnancy was complicated by eclampsia, pyelitis and nephritis and a stillborn baby was delivered at term causing a complete perineal laceration which was stitched at once. Puerperal infection forced the patient to bed for eight weeks and left a small vaginal rectal fistula. A nephritic condition persisted for about one year. A second pregnancy occurred in 1929 without any complications outside of a small amount of albumin during the last four weeks. One stitch was applied to the old fistula. The baby is living at this time and in good health. The mother has not been ill since that time, menstruates every twenty to twenty-five days (slightly irregular) and is very anxious to have another child. Could the fistula which noticeably discharges only following a laxative or could the lateral cervical laceration yet unrepaired seriously interfere with conception? If not, what artificial methods could be used to promote conception? What is the modern technique of artificial impregnation? How often should it be done? When is the most favorable time for it? What results may be expected? The husband has refused seminal examination. Is this considered necessary in such a case with the history of two previous conceptions? The husband is highly nervous probably as the result of hard mental work. What effect has general nervousness and hard mental work on the quality and secretion of the seminal fluid? Libido and orgasm are apparently normal with both husband and wife. Kindly omit name.

M.D. New Jersey

ANSWER—The rectovaginal fistula most likely plays no part in this patient's sterility and the cervical laceration, unless accompanied by cervicitis, is likewise of little etiologic significance. If however, there are evidences of infection of the cervix or of unusual heaping up of columnar epithelium on the portio accompanied by a profuse discharge this condition of the cervix may be a responsible factor in the patient's infertility. If the cervix is moderately abnormal, it can usually be corrected by means of the electric cautery, but if the damage is extensive a plastic operation may have to be performed. Before artificial impregnation is resorted to, it is highly desirable to examine the husband's semen, even though he was capable of fertilizing two ova previously. Even if the semen specimen shows actively motile spermatozoa, artificial insemination should not be practiced if there are evidences of infection in the semen, such as pus cells, for there is danger of infecting the uterus. Furthermore semen should not be injected into the uterine cavity until it has been ascertained that the patient's fallopian tubes are patent. This can readily be determined by means of the Rubin test.

On empirical grounds it may be advisable to perform a dilation and curettage before resorting to insemination, because not infrequently this operation is followed by pregnancy in previously sterile women. It is simpler and less troublesome than artificial insemination, which must be carried out many times. Both husband and wife must be told that attempts to impregnate the woman artificially will most likely have to be carried out many times over a period of months. Even then there may not be a successful result. The most favorable time to carry out this procedure is the ten days midway between the first day of one menstrual period and the first day of the next expected menses. The ideal time for conception to take place is at the time of ovulation, which usually occurs about

midway between menstrual periods. Since ovulation may occur any time from the tenth to the eighteenth day of the cycle and since the exact day for any particular woman cannot as yet be determined, it is advisable to inseminate three, four or five times during these ten days. The husband should be instructed to wash the penis with soap and water before coitus and the wife should take a sodium bicarbonate or salt water douche. There are four methods of procuring semen: masturbation, coitus interruptus using a small jar, coitus condomatus and natural coitus followed by aspiration from the vagina. The most aseptic method and one that is not too obnoxious is to have a small sterilized jar at hand before intercourse. At the time of the orgasm the semen should be ejaculated into this jar. The latter should be kept moderately warm and immediately brought to the physician's office. The patient is placed in the lithotomy position as for a vaginal examination and the vagina is carefully cleansed. The cervix is exposed with a bivalve speculum and the external os is further cleaned. However, it is not advisable to apply any antiseptic because this may destroy the sperm that are to be injected. The cervix is grasped with a tenaculum, and a uterine cannula is gently inserted into the uterine cavity. The semen in the jar is drawn up into a luer syringe and 1 or 2 cc of it is deposited in the uterine cavity very slowly. If the semen is injected too quickly, it will be expelled by uterine contractions. After the injection is performed the cannula should be removed slowly and the patient should lie quiet on the examining table for about thirty minutes. It is best to examine some of the semen just before each insemination to make certain that it is satisfactory. The results of artificial insemination cannot be stated with any degree of certainty because in this country at least not many individuals have practiced it. Abroad especially in France and Russia artificial impregnation has been practiced with a fair degree of success. Excessive nervousness and worry do play a part in deficient spermatogenesis but probably not enough to produce sterility over a period of years.

DIAGNOSIS OF IFU ULCERS

To the Editor—Please discuss this one. My patient is a happily married matron of 60 years. She has five children living and three dead at 7 years, 4 years and 6 months. None were premature. The Wassermann reaction is negative. She is thin, always slightly sallow and not markedly anemic. There is no pathologic condition except the present complaint and a chronic symptomless and obstinate colon infection of the bladder of five years standing, which might well be etiologic. In 1926 she had a small ulcer on one ankle. This healed slowly and did not return until early in 1931 when a similar one developed. Since then she has never been entirely free from fresh and healing ulcers. At one time these nearly banded both legs. They occur only from the middle part of the leg to the malleolus on both legs indifferently but nowhere else on the body. They recur irregularly, almost always at a new point and anywhere around a leg back or front. The ulcers vary in size from one eighth inch to several square inches and are irregularly rounded involving the whole skin yet not punched out. In the middle of one recently healed ulcer about 2 inches of the anterior tibial tendon sloughed out with the skin. New ulcers occur right beside or even partly superimposed on old healing ones progressing undisturbed to complete healing next to the fresh slough. The sequence of occurrence is as follows: Within a few hours a coalescent group of dark almost black clots about 2 mm in diameter appear under the skin as if the common supply of a group of capillary vessels were thrombosed. In the next few days or weeks this dark area sloughs out and the ulcer remains healing slowly after the manner of a varicose ulcer painful but only during the period of sloughing out. During this period the ulcerations ooze blood slowly not as a hemorrhage. When healing begins bleeding ceases. No pus collects unless there is secondary infection. This is kept in abeyance by constant cleanliness and antiseptic usually wet dressings. The problem is therefore rather prevention of new than healing of old lesions. Sodium iodine and mercury by mouth have been given. Mercury has been applied locally—the whole spectrum of chromatic applications. I have used salves, wet dressings and dry. Rest with elevation, atropine, insulin, light and heat therapy or what have you—nothing to date has made any decisive impression. The patient's general condition declines with imperceptible slowness. The general circulation remains unimpaired. The feet are now and then swollen. There are no varicose veins. I recognize no signs of Raynaud's disease or of endarteritis obliterans. Please omit name.

M D New York

ANSWER—A diagnosis of the condition described cannot be made. One would have to exclude primary or severe secondary anemias, leukemias of all types and other states leading to cachexia, as such patients may show the picture of "malum terebrans," rapidly spreading confluent areas of cutaneous gangrene. One would have to know whether the appearance of these gangrenous patches is preceded by general malaise, nausea and increase in body temperature, as these symptoms might suggest multiple, neurotic gangrene or Kaposi's gangrenous zoster. This lesion is probably on a neurotrophic basis and follows the course of the peripheral nerves. Erythema multiforme, nodosum and induratum are localized patches of

induration, which ulcerate and heal but the element of slough is not recalcitrant. Mycosis fungoides and Kaposi's sarcoma are slowly progressive malignant conditions but may heal locally and recur elsewhere. It is most unlikely that the patient is suffering from any of the peripheral circulatory disturbances or from any type of purpura, as the local lesion would not be apt to slough and heal again.

Multiple areas of gangrene may also occur as a result of infections, such as symbiosis of streptococcus with *B. welchii* or the symbiosis of a spirochete with a vibrio as in Vincent's gangrene. Infection with a diphtheria bacillus may also produce such areas.

Finally, one would want to know whether there is a persistent induration with lymphatic and venous block at these ulcerated areas, and whether or not because of the interference with venous and lymphatic circulation, this condition is self-perpetuating.

It would be futile to speculate on any form of treatment or prevention so long as the diagnosis is not made. The experienced clinical eye may determine more than pages of textbook knowledge could offer.

TONIC NEURONITIS OR MYELITIS OF PREGNANCY

To the Editor—Mrs. D. B. aged 38 after being pregnant six months developed swelling of the lower extremities and slight impairment of vision. At eight months the urine was loaded with albumin, the blood pressure was 210 systolic 130 diastolic and vision was quite markedly impaired. With the usual dietary and general treatment and with rest in bed the patient improved during the following two weeks the albuminuria diminished and the blood pressure came down to 180 but the visual disturbance grew progressively worse. September 1, two weeks before the expected time the patient had an uncomplicated labor and a live baby boy was delivered spontaneously. Forty-eight hours after parturition the patient became almost totally blind, developed a spastic paraplegia of both lower extremities (increased reflexes, Babinski loss of abdominal) and paralysis of both the urinary bladder and the rectum. The upper extremities and face were spared. The blood pressure remained in the vicinity of 180/120 and the urine continued to have a specific gravity between 1.006 and 1.008 with the presence of albumin. No casts were present. The blood examination September 28 revealed hemoglobin 60 per cent, red blood cells 3,310,000, white blood cells 23,200, polymorphonuclears 84 per cent, lymphocytes 11 per cent, mononuclears 5 per cent, nonprotein nitrogen 75 mg per hundred cubic centimeters. The blood Wassermann reaction October 7 was negative. Examination of the fundi showed the optic disks to be clearly defined. The retinal vessels over the remainder of the fundi were more or less obliterated by a grayish white exudate. The pupils were dilated and equal and did not react to light. In the past four or five days vision in the right eye has improved somewhat and the patient is able to move both lower extremities a little. The edema in the lower extremities is quite marked as yet. The patient had two other pregnancies, one eleven years ago but also associated with albuminuria and disturbance of vision and one eight years ago resulting in a stillborn child. I believe the patient has a nephritic type of toxemia resulting in cerebral hemorrhage and spastic paraplegia due to the added strain of labor. What do you believe is the diagnosis and where do you believe is the likely neurologic lesion? Kindly advise also as to prognosis and suggestions in treatment. Please omit name.

M D Michigan

ANSWER—The symptoms described in this case are most likely the direct result of the severe toxemia which the patient had. The syndrome has been called various names, chiefly polyneuritis, toxic myelitis of pregnancy and peripheral neuritis. Berkwitz and Lufkin (*Surg Gynec & Obst* 54:743 [May] 1932) reported four cases of this condition occurring during pregnancy and called it toxic neuronitis of pregnancy, because the nerve cells are involved as well as the peripheral nerves. The syndrome is usually observed in the first trimester of pregnancy after severe vomiting and it is not certain that the toxic symptoms which appear in the nervous system after delivery have the same origin as those which manifest themselves during pregnancy. In most of the cases that occur after delivery, infection and injury to the sacral plexus are noted. However in the present case the labor was uncomplicated and since the symptoms appeared only forty-eight hours after parturition, infection is probably not a factor in the paralysis. It is generally believed that the symptoms are due to auto-intoxication but the exact type of toxin involved is unknown. The mortality of the cases that occur during pregnancy is about 25 per cent, but this can be reduced considerably by interrupting the gestation early. If there is recovery in advanced cases, the paralysis may not clear up completely, because the nerve cells are often destroyed. Since in this case there is some improvement every effort should be made to institute regular active and passive movements to bring about further improvement and to prevent contractures of the extremities.

Whereas the paralysis observed in this case is rare, amaurosis is not uncommon in severe cases of toxemia of pregnancy especially in those with advanced chronic nephritis. The prognosis of the blindness is usually favorable for there is almost com-

plete recovery in most cases. There is, however, no specific way of hastening the recovery of the eyesight.

The diagnosis of cerebral hemorrhage is not correct for this patient. Such a hemorrhage could not produce the symptoms described without involvement of other parts, such as the face or upper extremity. Furthermore, the hemorrhage would have to be bilateral to account for the paralysis of both lower extremities. A type of hemorrhage that could cause the paralysis of the lower extremities with involvement of the bladder and rectum is a hemorrhage or thrombosis in the middorsal region of the cord. This, however, is highly speculative.

An effort should be made to build up the patient's resistance with special care to overcome the secondary anemia. A special diet must be prescribed. Because of the past obstetric history, the patient should be given specific instruction concerning contraception, as another pregnancy would be most hazardous.

UNDESCENDED TESTES

To the Editor—A man aged 25 married one year complains of sterility. Examination shows both testes undescended and situated in the inguinal canals. They are about one third the normal size. The scrotum is very small. The semen shows complete absence of spermatozoa. Sex desire and accomplishment are normal. The secondary sex characters are normal. Kindly discuss the prognosis following operation to bring the testes down into the scrotum with special reference to chances of the testes remaining in the scrotum and chances of securing spermatogenesis. Also discuss the possibility of securing descent of the testes and spermatogenesis through the use of anterior pituitary sex hormone. Kindly omit name.

M D New York

ANSWER—The operation for undescended testicles should be performed before puberty and the chances of causing the appearance of spermatozoa after operation in a man of 25 are slim indeed. It is true that there have been cases in which spermatozoa have been found after operation in an adult but in none of these cases is there any record of the absence of spermatozoa before the operation. In other words, such cases were probably rare cases in which the spermatogenic function persisted in spite of the abnormal position of the organs. In the case under consideration, spermatozoa are not present and it is extremely doubtful whether they will be present after the operation.

The chances of the testicles remaining in the scrotum after operation are good provided the operation is performed by one of experience in this regard. The Torek operation, described by Torek in the *New York Medical Journal*, Nov. 13, 1909, seems to be satisfactory as regards permanent results.

Many attempts have been made to cause the descent of the testicles by the use of injections of various endocrine preparations, but most of these have been unsuccessful.

LUPUS ERYTHEMATOSUS

To the Editor—I have a patient whom I have been treating for lupus erythematosus. I have been giving him bismuth salicylate 2 grains (0.13 Gm.) every four days for thirty-four doses. He has shown no apparent benefit so far. Would there be any value in giving him any more bismuth salicylate? About four years ago he received a course of gold sodium thiosulphate which cleared up his condition entirely but he showed some reaction from the gold. About two months after discontinuance of the gold the condition reappeared. Would he be more apt to show a reaction on repetition of the gold? How long is the usual treatment before any favorable action is shown if any benefit would appear?

A F JENSEN M.D., Rugby N D

ANSWER—The patient has already had more than 4 Gm of bismuth salicylate which exceeds the amount generally considered the maximum for a course. It is not likely that any benefit will be obtained from further use of the drug at this time and no more should be given at any rate for at least a month. If gold therapy is contemplated it should not be started until an opportunity has been given for elimination of the bismuth. A careful check on the condition of the kidneys is particularly important during the treatment of lupus erythematosus with any heavy metal. When gold therapy is begun more than ordinary care should be exercised because of the history of slight intolerance during the previous course but sensitization to the drug is not inevitable. It may be well borne at this time. The dosage in the former course may have been too high.

No statement of the length of treatment necessary before good results appear can be made. Lupus erythematosus is a most capricious disease responding sometimes to a few doses of the gold preparation at other times showing improvement only after a long course or not at all. The general opinion at present favors small dosage 0.1 Gm being considered the maximum even though the results are slow to appear. A course of twenty injections is not unusual.

It should not be forgotten that there are older methods of treatment of this disease that frequently succeed when the heavy metals fail. Application of tincture of iodine until the skin becomes dry and somewhat irritated, application of a mixture of one part phenol to four parts of lactic acid painted on once every five days until irritation appears, freezing with carbon dioxide snow and mild radium exposures, are indicated according to the chronicity of the lesions. Local treatment is indicated during the rest period advised for the case under discussion.

LOSS OF BEARD AFTER BULLET WOUND

To the Editor—I had as a patient about a month ago a white man aged 39 who had been shot through the head with a 0.22 caliber bullet. The bullet entered the left side of the head just below and posterior to the junction of the external angular process of the frontal bone and the zygoma. The bullet crossed downward and to the right fracturing the floor of the bony orbit chipping the posterior wall of the left antrum passing through the throat and lodging in the right side of the neck about the angle of the jaw in which site it was extracted. At the time of the injury some numbness was noticed about the left side of the face this gradually disappeared but sensory sensation has not returned to normal in several areas over the left side of the face which areas can be circumscribed by the use of a pin. The patient also complains of a numbness of the seventh and eighth upper molars. About two weeks ago he noticed that the beard on the left side of his face had practically ceased to grow and that much of it was falling out. The loss of hair extended somewhat up on to the temple and over the left ear. There was a sharp line of demarcation at the chin and upper lip and with a day's growth of beard the difference between the sides of the face were very noticeable. Is it possible that the loss of the beard may be due to the injury of some of the branches of the fifth cranial nerve if not what explanation can you give for its loss? What do you consider the prognosis in this case? There was at no time any motor disturbance of the facial muscles the trouble having been at all times strictly sensory in character.

O J HANSEN M.D. Redding Calif

ANSWER—Growth of hair depends on two factors, the vasomotor activity of the skin and the trophic nerve supply to the skin. The sympathetic nerve supply to the skin of the face passes out from the ram communicantes of the first and second thoracic segments and then along the branches of the external carotid artery. It is inconceivable that these fibers could have been interrupted. The question then is whether the trophic nerve supply to the skin could have been interrupted. The region described as affected by loss of hair is supplied by the maxillary division of the trigeminal nerve except the chin, which is supplied by the mandibular division. If the whole maxillary nerve had been injured, the patient would have complained of numbness in all the upper teeth on that side. Consequently it must be assumed that only certain branches were injured. The numbness of the last two upper molars indicates that the posterior superior alveolar branch was injured. Probably the sphenopalatine ganglion did not escape, and near it the zygomatic nerve leaves the maxillary nerve and divides into two branches, the zygomaticofacial and the zygomaticotemporal which supply the skin over the area in which the patient has lost his hair. It is interesting to note that after section of the sensory root of the trigeminal nerve no difference in the growth of hair on the face has been noted. On the other hand, after removal of the inferior cervical and first thoracic sympathetic ganglions the hair tends to grow more strongly on the side operated on. The prognosis for the return of hair is probably good, as the face is so well supplied with sensory and trophic fibers.

ENDOCRINE IMBALANCE IN MENOPAUSE

To the Editor—A white woman aged 45 who is entering into the menopause, was seen in a state of excitability and almost collapse. Her pulse was 112 blood pressure 160 systolic 150 diastolic. She complained of a feeling of pressure in the chest particularly the pericardium and a paralyzed feeling down the left arm. May the endocrine imbalance of the menopause be responsible for such angina-like circulatory disturbances? Please omit name.

M D Wisconsin

ANSWER—The manifestations exhibited by this patient may all be explained by the changes that take place in the body at the time of the menopause. Tachycardia is not infrequent and this is usually due to some change in the nervous system. It may, however, be due to a mild degree of hyperthyroidism which results from the cessation of ovarian activity. Excitability is common during the menopause especially in those women who were nervous before the change of life took place. In many women there is an elevation of the systolic blood pressure at the menopause caused most likely by instability of the vasomotor system. Usually the diastolic pressure is not increased commensurately with the systolic and hence the pulse pressure is increased. The sensation of pressure in the chest and the paralyzed feeling may be nervous or vasomotor in origin.

SEXUAL FRIGIDITY

To the Editor—Mrs. P. C., aged 34 married four years has never had any children and no serious illness. She had two self-induced abortions about two and three years ago each at about two months. She had no bad after effects and in a few weeks menstruation became normal. She has never had a gonorrheal infection but has had a mild leukorrhea during the last eight or ten years. The patient began menstruating at about the age of 12 and has always been regular although she has had considerable pain during the first day or two. The flow lasts about four to six days. The heart, kidneys and bowels are normal. The appetite is good, the weight is constant at about 165 pounds (75 kg.). She uses alcoholic beverages moderately. About a year ago she had an attack of what she thought was acute appendicitis and went to her doctor who diagnosed it as such and operated on her. He told her that he removed the appendix which was somewhat diseased and that he also had to remove both her tubes which were badly diseased and that her ovaries and other organs were normal. She says that she and her husband who is 44 years old and in good health but with a history of gonorrhea when 18 years old have had sexual intercourse from five to ten times a month until her operation one year ago. She says that she was always passionate and that she frequently experienced from three to seven orgasms during one act of coitus which often lasted from thirty to forty five minutes before her husband would have an orgasm. Following her operation they have had coitus less frequently because she has lost all desire for it. She says that even though the act is prolonged she has not experienced even one orgasm in the last year. She has not told her husband of this loss but pretends to have them as before. She has come to me for treatment and advice. Vaginal and bimanual examination does not show anything abnormal. The clitoris and labia are normal. I have known this condition to exist in a few women after normal confinements but it has gradually disappeared in each case. I should like to know the cause of this condition and what treatment can be recommended. Please omit name.

M. D. North Dakota

ANSWER—If only the tubes and appendix had been removed there is no reason, except perhaps a psychic condition, for the patient to experience any difference in her sexual passion. The query does not state whether or not there has been any menstruation since the operation, if not it may be that the ovaries were also removed and this would account for the lack or diminution in sexual passion. In case menstruation has continued this possible reason may be excluded. It often happens that, after any severe operation on the female genitals, especially when permanent sterility must result there is a temporary loss of sexual desire. Treatment with estrogenic substances may be tried as well as the sensitization of the vaginal mucous membrane with the galvanic-sinusoidal current as described by Huhner (*Medical Times* 60 237 [Aug.] 1932).

MIGRATING PHLEBITIS

To the Editor—A woman aged 64 has been under observation for several months for what appear to be recurrent attacks of phlebitis. Her past history is essentially negative. Her present illness dates back about four months beginning with slight pain in the left arm and followed by great swelling of the entire limb twelve hours later. The swelling subsided in about one week and since that time all her limbs have been involved at various times and at present both lower extremities and the left arm are greatly swollen and tender. All the attacks appear similar. The first inkling of any trouble is that the patient complains of pain along the course of one of the superficial veins in one of her extremities. A few hours later the area about this vein is painful and tender with redness and heat along its course and the vein can be palpated as a hard tender solid cord with occasional nodules on it. About twelve hours later the extremity begins to swell and about twenty four hours after the onset the entire limb is about twice its normal size, extremely tense and very painful. During one attack of phlebitis in the right lower extremity the patient developed a sudden severe pain in the right side of the chest with a friction rub and a few moist rales over the painful area. This was diagnosed as pulmonary infarct. Her temperature during these attacks has usually been normal the highest at any time being 100.6 F. Besides the recurrent involvement of the extremities the patient has complained of constant severe epigastric pain with loss of appetite and some nausea but no vomiting. Physical examination otherwise has been essentially negative. The blood pressure is 108 systolic 70 diastolic. Urinalyses have been negative. The blood count shows a mild secondary anemia, the platelet count averages about 300,000, the coagulation time is four minutes, the bleeding time is three minutes. Repeated blood cultures have been negative and blood chemistry was negative except for a slight rise in nonprotein nitrogen which was 45.1 mg. per hundred cubic centimeters. The stools were repeatedly negative for blood or parasites. Stomach analysis showed a slight decrease in free hydrochloric acid. A gastro-intestinal series was negative except for slight gastroptosis. The patient has been on alkaline powders and given sodium citrate intravenously to the point at which alkalosis was produced but she has gone along having recurrent attacks of this peculiar type of phlebitis. Any suggestions regarding diagnosis and treatment will be appreciated. Kindly omit name and address.

M. D. New Jersey

ANSWER—The description of the case would suggest the diagnosis of a migrating phlebitis, characterized by recurrent attacks of phlebitis in different segments of the venous system.

It is a low grade infection, to which the venous intima is specially sensitized and may affect all veins of the body. Thus it is not too far fetched to suggest that the severe epigastric pain with nausea and loss of appetite may be an identical involvement of certain segments in the portal system. Thrombophlebitis of the splenic vein would manifest itself in a splenomegaly with gastric or esophageal hemorrhages, while mesenteric thrombosis produces severe intestinal colics, with bloody or mucous stools.

Blood cultures are usually sterile between attacks, but during an acute attack, particularly if it is accompanied by a chill a positive blood culture may be obtained. When routine blood cultures fail, a competent bacteriologist may still obtain positive results by eliminating many inhibiting factors. Another possibility is the excision of a small superficial inflamed segment, which should be subjected to competent bacteriologic study. In the possession of a positive culture, a formaldehyde killed autogenous vaccine offers the best therapeutic approach. A large number of intravenous antiseptics, such as gentian violet, mercurochrome and acriflavine base have been suggested. Of these, acriflavine base seems worthy of trial. The dosage is 50 cc. of a 1:1,000 solution and may be repeated every few days. While the process is undoubtedly on an infectious basis, thus necessitating a careful search for initial focus, a definite allergic element that is a hypersensitivity of the intima to this particular infection is quite likely. The treatment of the acute stages may be best accomplished by small doses (from 100 to 125 roentgens) of x-rays with deep filtration. The prognosis of such cases is unpredictable, a pulmonary embolism being often the cause of death. Sometimes however the process gradually subsides, leaving residual symptoms of venous obliteration.

SMALL PENIS

To the Editor—I have under my care a man aged 28 normal in every respect and well developed except for the genitalia. The penis is undersized about 1½ inches long although the testicles are normal. He has developed an inferiority complex to such an extent that it is affecting his general health. He states that he derives no satisfaction from sexual intercourse, because of the psychic mental disturbance that he cannot satisfy the opposite sex. He has tried developers and "messengers" without my recommendation but without any success. He is willing to submit to any kind of a plastic operation if it is possible to alleviate his condition. Kindly inform me of the nature and danger of this operation also of any injection or serum that may be helpful in his case. Kindly omit name and address.

M. D. Pennsylvania

ANSWER—There is no plastic operation which can have the slightest effect on this condition and no injection treatment can help. The penis has two functions, urination and coitus. If both these functions can be accomplished, the patient should not worry. In other words, no matter how small the penis may be in the flaccid state as long as during erection it gets large enough to enter the female to her and his complete satisfaction nothing more should be expected. The trouble with these patients is that when exposed in a male swimming pool or similar institution they are terribly ashamed of the small size of the penis.

PERSISTENT BILIARY FISTULA

To the Editor—I have a case of persistent biliary fistula following a gallbladder drainage for a suppurative cholecystitis. My patient convalesced very nicely after the drainage was done and the wound closed in about six weeks but opened again in a few days and drained a small quantity of bile since which time it has been closing and opening every two or three days emitting a small quantity of bile. Just before it opens each time the patient has a feeling of uneasiness and fullness in the gallbladder region and as soon as the fistulous tract opens and releases the bile drainage there is relief for a few hours. The patient feels fine in every other way there are no clay colored stools and he eats and sleeps and has regular bowel evacuations. I am writing to ask what the latest treatment for this condition is. Several authors are of the opinion according to all I can find on the subject that these conditions should be left alone and that the patient must go through the years wearing a dressing. It would seem to me that an attempt could be made to close this fistulous tract unless the lumen of the common duct will not take care of the biliary secretion. I have found the suggestion that in these suppurative cases there is a fibrosis which takes place that causes a partial obstruction to the flow of bile through the common duct.

E. L. HUSTEAD, M. D. Scribner, Neb.

ANSWER—Failure to obtain spontaneous closure of a gallbladder fistula following cholecystostomy is almost invariably due to obstruction of the cystic duct. The presence of bile in the fistulous drainage indicates partial or intermittent obstruction. Suppurative cholecystitis without stones is rare. Therefore, the presence of a stone impacted in the neck of the gallbladder or in the cystic duct should be assumed. Such a fistula has no relation to pathologic changes of the common

duct It is obvious in this instance that there is no obstruction of the common duct and, since there is no colic, probably no stone Suppurative cholecystitis treated conservatively (cholecystostomy) should in most instances be followed by a cholecystectomy When a fistula persists, nothing but cholecystectomy will effect a certain cure

DETERMINATION OF pH VALUE OF SWEAT

To the Editor—Has the determination of the pH value of the sweat by indicators applied to the skin been accepted as being of scientific value in the diagnosis of disease?

WILLIS P. BAKER M.D. Santa Ana Calif

ANSWER—The determination of the hydrogen ion concentration of sweat has not as yet been shown to be of any practical value in diagnosis The perusal of a dozen current laboratory manuals reveals no consideration given to sweat None of a dozen internists extensively engaged in clinical medicine and investigation when questioned stated that they ever had occasion to desire such information The laboratory connected with a large clinical and research institution reports that such determinations are requested on the rarest occasions, and then only for research purposes

Such determinations are of interest in physiologic studies on water balance and acid base equilibrium of the body and also in certain skin diseases The pH of sweat is reported to be altered at times in certain rheumatic and other diseases

EARLY DIAGNOSIS AND TREATMENT OF SYPHILIS

To the Editor—I wish to protest against the advice given to M.D. New York (THE JOURNAL August 26 p 731) Syphilis can be contracted only through an abrasion and only a small percentage of those exposed ever become infected Therefore your advice to give arsphenamine before any symptoms develop condemns the person to a life of misery and worry thinking he has syphilis with no means of ever being certain Your advice is the same that has been condemned in regard to lesions on the penis in which spirochetes cannot be found It is unfair to the patient to subject him to worry expense and danger of arsphenamine treatment on the mere supposition that he may have contracted the disease

GEORGE R. LIVERMORE M.D. Memphis Tenn

ANSWER—The correspondent is right The statement that the other course waiting for a definite diagnosis before giving any treatment is much the wiser was not emphatic enough Some nervous patients however, are insistent on immediate action and if after having the matter explained to them they still insist maintaining that they will worry less and promising to remain under surveillance for the longer period the treatment may be used It is not to be advised otherwise

NUMBNESS OF ARM AND HAND

To the Editor—A man aged 40 a robust farmer has had numbness (duration of four months) of the left arm and hand occurring when he drives a car or when he is milking and at other times during the day He awakens with the part asleep I have examined him carefully checking every item in the periodic health examination form and the results are negative except that there is atrophy of the right testicle following an attack of mumps and the left ear drum is perforated I have sent the blood for a Wassermann test The patient is taking potassium iodide 10 drops three times a day Please give me an idea as to diagnosis and recommend a treatment Do not publish my name

M.D. Washington

ANSWER—From the history one would judge that this patient in certain positions of his left arm has a pressure on the brachial plexus possibly pressure on the subclavicular artery

One of the things to be considered is the possibility of a cervical rib A picture should be taken of the cervical spine to rule this out and also a roentgenogram of the upper part of the chest to rule out any tumor mass The cervical rib, however, is the most probable cause of this trouble.

PEELING OF SKIN

To the Editor—A young woman who previously had suffered some skin disorder was given a face peel by a plastic surgeon Acid was used Now the patient's skin is very thin and sensitive to sunlight wind and the like What treatment would properly restore the skin texture and eliminate the subjective sensitiveness to sunlight? Please omit name

M.D. Chicago

ANSWER—This case illustrates the difficulty of using the peeling treatment without producing undesirable results For this reason it is little used, even by those skilled in dermatologic work Time will restore the texture and resistance of the skin, but in the interval it should be protected against the effects of light and wind by applications of cold cream and face powder All manipulation should be gentle, and the mildest superfatted soap should be used or oatmeal or bran water used in place of soap

VITILIGO

To the Editor—A patient has heard that Dr. Vilray Blair of St. Louis is having pronounced success in the treatment of leukoderma (vitiligo) and is anxious to learn more about the doctor and his method Can you give me any information concerning this?

H. J. HARRIS M.D. Westport on Lake Champlain N.Y.

ANSWER—The letter was referred to Dr. Blair, who writes Vitiligo is not a disease in itself and therefore any operative procedure such as skin grafting would be out of order No form of treatment is known that influences the condition Rarely cases clear up spontaneously and the skin assumes normal appearance

ABSORBABILITY OF CALCIUM FROM BOWEL

To the Editor—Would you please tell me which of the three calcium salts is absorbed from the intestine in the greatest percentage calcium chloride calcium lactate or calcium gluconate?

M.D. Illinois

ANSWER—There is no essential difference in the degree of absorption of these calcium salts as the first thing that happens when such salts enter the complex chemical mediums of the gastro intestinal tract is that the chemical law is obeyed which postulates that in a mixture of ions the least soluble combination will be formed and thrown out of solution The extent to which the resulting insoluble compound will be absorbed will depend on other conditions such as the prevailing hydrogen ion concentration, rather than on the original combination

CONSTIPATION IN A CHILD

To the Editor—Can you recommend a useful treatment for chronic constipation in a boy aged 6 years? Roentgen examination reveals a hypotonus and dilatation of the sigmoid Nearly all forms of ordinary laxatives have been tried as well as an abdominal belt The child will go several days without a bowel movement until an enema relieves the situation The presence of an anal fissure which becomes painful makes it nearly impossible to allow a long delay in evacuation Please omit name and address

M.D., New Jersey

ANSWER—Oil should be used from below and from above An enema should be used every evening to be retained over night until the oral dose of liquid petrolatum or its emulsion has resulted in the disappearance of all lumps from the stools The use of the oil should be continued until the anal fissure has been healed, if necessary by surgical means Then a constant attempt should be made to wean the boy of the necessity of using the oil by giving him a ballast-rich diet while gradually reducing the quantity and frequency of use of the medicine

EFFECTS OF COID IN BODY

To the Editor—Will you please give me information and references concerning gold poisoning? I am particularly interested in skin manifestations of gold poisoning and also in the possibilities of poisoning from metallic gold What are the possibilities of poisoning resulting from ingestion of pills said to be coated with 23 karat gold? This question has come up in connection with a medicolegal case

WILLIAM W. STRAUB M.D. Huntington W. Va.

ANSWER—Metallic gold such as is used for pill coating is absolutely harmless as none of it is absorbed the body not having aqua regia at its disposal to dissolve it Soluble gold salts such as gold and sodium chloride are much less toxic than the salts of most other heavy metals but are capable of producing gastro-enteritis and spinal paralysis When such salt is injected intravenously the toxic effects suggests arsenic poisoning

TORTICOLLIS DUE TO RUPTURE OF MUSCLE

To the Editor—I have under my care an infant now aged 7 months with a congenital torticollis due to a hemorrhage into or a rupture of the sternocleidomastoid muscle during birth. The tumor was first noticed when the child was 2 weeks old and is still present and about the size of a pigeon's egg. The muscle is still spastic. As yet there is no tipping or twisting of the head. There is no limitation of passive motion of the head but active motion is reduced about one third of the normal range. There is some flattening of the opposite occipital region due to the child's favoring the muscle during sleep. What may be done to correct the condition and when and at what age is surgical intervention indicated? Please omit name.

M D Ohio

ANSWER—"At 7 months or older little can be accomplished by conservative measures. However it may be worth while to give passive exercises to try to overcome the deformity. Most of these cases require surgical intervention. The age of choice is about 3 years. Before this age, the skin is more liable to give trouble from irritation by the orthopedic dressing or appliance. Some favor earlier operative measures to prevent the development of facial asymmetry but the asymmetry that develops in a child up to 3 years gradually disappears after the operative correction."

HEAD ROLLING OF INFANTS

To the Editor—I call attention to a remarkable feature—a feature suggesting a clue to treatment—of the case of head rolling, described in Queries and Minor Notes in THE JOURNAL Nov 18 1933 page 1661. This feature is that the head rolling occurred (1) while the patient was falling asleep (2) when he was incompletely awakened and (3) during the lighter phases of sleep (during uninterrupted sleep it never occurred before midnight and it was worse after 4 a m). The occurrence of the symptom under only these circumstances is reminiscent of a phenomenon observed in some cases of narcolepsy.

In a recent paper (The Pathogenesis of Narcolepsy with a Consideration of Sleep Paralysis and Localized Sleep *J Neurol & Psychopath* 11 1 [July] 1933) I pointed out the comparative frequency in narcolepsy of a phenomenon designated as sleep paralysis. This phenomenon manifests itself in two forms (1) predormital paralysis in which the patient while falling asleep finds himself paralyzed (2) postdormital paralysis in which the paralysis occurs immediately after awakening from sleep the patient being unable to move for an appreciable length of time after having regained full waking consciousness. Clinical and laboratory data justify one in regarding sleep paralysis and certain other phenomena of narcolepsy as instances of what Pavlov called localized sleep—the manifestations of a state in which inhibition is for the moment localized in certain parts of the brain instead of being as it presumably is in the deepest form of sleep generalized.

In the case described by your inquirer the fact that head rolling occurs not during deep uninterrupted sleep but during light sleep as well as during the predormital and the postdormital justifies one in asking whether the mechanism of the symptom is related if only remotely to the mechanism of narcolepsy. The propriety of the question is a little enhanced by the fact that in many cases of narcolepsy there is great motor restlessness during sleep. This restlessness during sleep may be regarded as a special instance of localized sleep the motility substrate being more or less uninhibited while the substrate of consciousness is in a state of relatively deep inhibition.

For these reasons one would in my opinion be justified in recommending to your inquirer that he treat the patient with ephedrine a drug that is virtually a specific in idiopathic narcolepsy. Obviously treatment with ephedrine is in this case only an experiment. Should the head rolling clear up under this treatment one might properly suspect that the mechanism of the symptom is (in this one case) related in some way to the mechanism of narcolepsy. In order to settle the question as decisively as possible it is to be hoped that if the child is given ephedrine he will during the period of this treatment receive no bromides or phenobarbital.

MAX LEVIN, M D Harrisburg State Hospital Harrisburg Pa

PERSISTENCE OF SPERMATOZOA AFTER VASECTOMY

To the Editor—I note that in THE JOURNAL Nov 18 1933 page 1663 a physician of North Dakota asks how long it takes after a bilateral vasectomy for the spermatozoa to disappear from the semen. The answer printed states that in all probability one or two ejaculations should be sufficient to remove the spermatozoa.

I have carefully studied this subject in a series of some 200 vasectomies done to effect sterilization. At first I asked these men to bring in condom specimens for the first two or three ejaculations. Finding living spermatozoa always present I began to lengthen the time at which the ejaculated specimens were to be brought.

I found in brief that spermatozoa are often encountered alive up to the twenty-first day and infrequently as long as the twenty-eighth day. I have no cases in which the vasectomy was proved to be complete in which spermatozoa appeared alive later than the twenty-eighth day.

These data were accumulated in order to advise patients as to when they would be sterile following vasectomy. It was my desire also to obtain some idea as to what the length of life of a spermatozoon actually is. I now believe this length of life to be twenty-eight days. I have asked many patients to do their best to prevent ejaculation in the interval up to twenty-eight days and to bring in an ejaculated specimen on the twenty-eighth day. In such cases I often find occasional live spermatozoa still feebly moving among numbers of dead ones.

Book Notices

The Eradication of Bovine Tuberculosis By L. Jordan. Medical Research Council Special Report Series No 184. Paper. Price 2s. Pp 104. London His Majesty's Stationery Office 1933

This is a monograph bringing down to date the labors of the royal commission on tuberculosis. It has a historical setting in that the royal commission on tuberculosis 1904-1911, firmly established a finding that had been foreshadowed by the previous royal commission of 1895 and earlier workers with Charles Creighton in 1881. The essential fact is that bovine tuberculosis may readily be communicated to human beings and that tuberculosis is not the only infectious disease conveyed by milk, but it is by far the most important and insidious. This report by Jordan describes the results of a large scale experiment in the southwest of Scotland covering an area of some nine square miles to the northeast of Mauchline, Ayrshire. The area was bounded by good roads and contained thirty-seven farms, thirty of which are included in the scheme. The investigation was carried over a three year period and of the thirty herds participating, twenty-eight made substantial progress, twenty were free from infection at the end of the experiment while eight showed substantial reductions in the number of reactors. The report gives a good example of the way in which a field investigation, carried out under careful scientific control may lead to conclusions of great practical importance. It shows that eradication of tuberculosis from heavily infected herds is by no means an insoluble problem and demonstrates clearly the problem in tuberculosis eradication which can be achieved by providing the relatively small incentives of free tuberculin testing and free expert advice. The author ably covers the subject of the need for eradication pointing out the losses due to bovine tuberculosis approximating £750,000 per annum with 2000 deaths among human beings and at least 4,000 fresh cases annually. The methods of tuberculosis eradication are grouped under Ostertag's method, Bang's method and the slaughter method and the pros and cons for these outlined. In addition, the double intradermal test is interpreted and its reliability evaluated. The entire presentation is couched in simple and understandable language and the data are presented in an elucidating fashion. Four appendices are included, giving valuable details of methods of eradication in the experimental area of individual herds, of cost of eradication and of the measures taken in various countries to combat bovine tuberculosis, including Great Britain, Germany, Denmark, Sweden, the United States and Canada. To those interested in any of the phases of tuberculosis eradication and prevention, this monograph can be highly recommended. It contains the details of an experimental test well worth knowing. It does not fail in elucidating the economic side of the problem as well as the purely scientific. It takes into consideration not only the theoretical but also the practical and although some might wish to be more radical in enforcing eradication it ably defends the stand taken. All in all the author and the Medical Research Council are to be complimented for the high character of this report.

The Treatment of Rheumatism in General Practice By W S C Copeman M A M B B Ch Assistant Physician West London Hospital. With a foreword by Sir William Hale White K B E M D F R C P Consulting Physician to Guy's Hospital. Cloth. Price \$3.25. Pp 215. Baltimore: William Wood & Company 1933.

Life is being prolonged as the control of acute infections becomes more successful. It behooves the profession to make that life happy by keeping it healthy, to save health as well as life. Chronic rheumatism constitutes one of the greatest menaces to an active, happy existence. This group of diseases must not be viewed fatalistically or considered with a defeatist's attitude, as an act of God. The belief that chronic rheumatism is unworthy of the intelligent consideration of medical practitioners must be destroyed. The author is a member of the staff of the British Red Cross Clinic for Rheumatism in London where each year many thousand patients register for treatment. In this book the author has attempted to survey critically the various therapeutic methods from the attitude of the general practitioner and not of the specialist, and to describe in full detail the rationale and technic of those which are most useful and readily available to the busy physician.

General textbooks on the practice of medicine are often niggardly in their presentation of treatment for these conditions. Monographs are considered generous that devote one third of their pages to treatment. The title of the book is well earned, as shown by the fact that 70 per cent of its content is concerned with a discussion, full and detailed, on methods of treatment. The author has thus happily begun where others have generally left off. Prescriptions are given, dosages of vaccines, details of manipulative procedures, dietary outlines, minute directions regarding the various forms of physical therapy available for home and office use and even the technic of a mustard pack and bath. Thereby this book should be most helpful in planning a progressive, rational, curative program and its cost subsequently earned by the purchaser many times over. Though generous in these details, the author has frankly not attempted to do more than outline in briefest detail clinical and etiologic phases of the various diseases discussed. As a handbook of treatment, its clinical descriptions are perhaps adequate and on this ground the absence of all but the most cursory consideration of pathology and etiology are excusable. For the latter details, so necessary to the assured and enlightened physician, reference could well be made to any one of several recent monographs on chronic arthritis and the rheumatic diseases.

In parts I and II chapters are devoted to acute rheumatic fever, chorea, acute muscular rheumatism and fibrositis, sciatica, neuritis, rheumatoid (atrophic or infective) arthritis, hypertrophic (osteo) arthritis, climacteric arthritis and spondylitis. With the discussion of each subject an outline of the author's recommended treatment is given including the indications for his original treatment of intractable rheumatism by repeated transfusions and injections of insulin. In part III, various forms of treatment are more fully considered: medicines, diets and vaccines, nonspecific protein therapy, physical methods such as manipulation, baths, colonic therapy and actinotherapy, endocrine substances, orthopedic methods including the use of splints, treatment given in spas, climatic treatment and other methods. Chapters are also devoted to the relationship necessary between an arthritic patient and his physician, also to osteopathic treatment and nature cures. A few data on prognosis, a subject so rarely considered in most books on the subject, are given in the concluding chapter.

Many readers will not share the author's broadmindedness regarding osteopathy or his optimism concerning the possible value of several forms of treatment advocated, particularly colonic therapy. The case for intestinal therapy is certainly not strengthened and its indications are again but weakly outlined. Nothing new is given to justify the continued use of the term 'climacteric arthritis,' which still remains a vague entity. In deference to its American public the book should include at least an outline of several forms of treatment here widely advocated in the last five years, particularly more details of the newer attempts at desensitization and immunization in rheumatic fever and chronic atrophic arthritis. A consideration of gout, a disease so regularly mistaken for rheumatic fever or chronic arthritis, should certainly be included but is omitted entirely. The occurrence of strange and unexplained English abbreviations is annoying, and the omission of bibliographic

references to the eighty authors mentioned seems inexcusable. It has been said that the best treatment for a patient with rheumatism is for one doctor to send him to another. With this book a physician can with no little assurance at least begin to be that other. It is a useful and practical little volume that one could wish to have written oneself.

L'épiphyse. Étude embryologique, histologique et anatomique clinique. Par le Dr Jean Calvet, professeur agrégé à la Faculté de médecine de Toulouse. Préface du Professeur Christian Champy. Papier. Pp. 149 with 63 illustrations. Paris: I. B. Baillière & Co. 1933.

In no field of medicine are the results of experimentation—well conceived and controlled and under the direction of masters of the art—so paradoxical as in endocrinology, and more particularly in the domain of the pineal gland (epiphysé), and Calvet shows this to perfection. The work contains the orthodox chapters beginning with history, going through embryology, anatomy, histology, physiology, clinical studies and pathology, and including even treatment of diseases of the pineal gland. It is a real satisfaction to read through these chapters of solid material with no padding. The author describes thoroughly the difference between the vestigial eye of the amphibia and the real pineal secretory tissue attached to it. In this tissue many will be interested to know there are smooth muscle fibers, pigment cells and giant cells as well as typical secretory epithelial tissue. The real difficulties arise in the physiologic domain. Here whether it is a matter of extirpation of the gland, grafting or feeding experimentation, the results are contradictory. To illustrate: Male chicks, from 3 to 5 weeks old, were epiphysctomized by Goa. Those that survived grew much faster than the controls and sexual maturity with secondary sex characteristics appeared early. But when the same work was done on females, no changes were apparent. Other investigators found that after epiphysctomy sexual maturity was retarded and growth impeded. In feeding experiments likewise most authors describe a retardation of growth and development, though again others of equal authority show increase of growth and sexual maturity. Even in grafting, fresh glands, one might expect a certain unanimity of result. Mais non! The author gives his results in this field a lack of growth, abeyance of sexual maturity and general retardation. Again other methods in other animals give just the reverse picture. The monograph presents these various views in excellent contrast and without bias. The clinical studies on human beings are excellently presented. In short no one in the field of endocrinology can well be without this exhaustive even though modestly short, treatise on the pineal gland. There is a bibliography of more than thirty pages carefully compiled, which should be a mine of interest and importance to the student. After a complete reading no doubt should remain in the mind of the importance of the pineal as a gland of internal secretion. The language of the text is quite simple and easily understandable by those with only a slight knowledge of French. The entire treatise is admirable, timely, well balanced, with numerous explanatory illustrations, and is well worth adding to one's library.

Practical Anatomy. By Six Teachers. Edited by F. P. Stibbe, F.R.C.S., Senior Demonstrator in Anatomy, London Hospital Medical School. Cloth. Price \$7. Pp. 719 with 337 illustrations. London: Edward Arnold & Company, 1932.

The six teachers collaborating are William Wright, London Hospital Medical School; Thomas Yeates, Middlesex Hospital Medical School; J. S. B. Stopford, University of Manchester; S. E. Whitnall, McGill University; Montreal; Mary F. Lucas Keene, London School of Medicine for Women; and E. P. Stibbe, London Hospital Medical School. The book is a laboratory manual for dissection of the dead body. As such it is thorough and practical. It obviously represents long and faithful work in the dissecting room. The technique of dissection is excellent and the whole method and spirit are practical. The illustrations consist of diagrams and drawings; they are well selected and of great help to the student. It is probably the most thorough of the laboratory manuals of dissection available. The nomenclature used does not conform with that recommended by the International Association of Anatomists (B.N.A.) with that of the later Commission on Nomenclature or with that of English works such as Cunningham's Textbook of

Anatomy. The substitution of English or of any other local nomenclature for the older and international Latin is cause for regret. It leads to logical inconsistencies and confusion in some cases, as when "outer" and "external" are made synonymous with "lateral." The text contains few references to the medical or surgical application of anatomic facts. It leads the student into a study limited strictly to the anatomy of the dead body. However conscientiously anatomists may endeavor to limit the study and thought of students to pure morphology, they set themselves in the effort an almost impossible task. The intelligent student is curious about how these structures come to be and about what they do during life. After all it is the living body in which physicians are interested. The vital processes which these structures serve and represent are the studies of significance for both biologists and physicians. The almost total omission of them from a book on anatomy, although sanctioned by custom is not in accord with the best science or the best pedagogy.

Colour Vision Requirements in the Royal Navy. Reports of the Committee upon the Physiology of Vision. VII. Medical Research Council Special Report Series No. 18. Paper. Price 1s. 1p. 3s. London: His Majesty's Stationery Office, 1933.

This work was originally undertaken at the request of the Admiralty and was completed with the aid of facilities offered by the British navy. Unsatisfactory testing of color vision with too high a percentage of rejections by some tests contrasted with well color perception by many of the men passed by other tests led to the fairly complete study here presented. Various types of occupations called for varying degrees of acuity of color perception so that finally the various grades in the navy were classified according to color perceiving requirements. The conclusions of the committee numbered fifteen of which the following seemed to be the most important. The final examination of the color vision of candidates should be undertaken by ophthalmic surgeons equipped with adequate apparatus. Practical tests at sea or in harbor are dangerously unreliable when used alone. For present use the Ishihara test and the Eldridge Green lantern test are recommended but no one technical test is regarded as being infallible. A great part of the pamphlet does not lend itself to abstract but must be read in the original by any one interested. Only a short bibliography is appended.

Multiple Sklerose und Erbanlage. Von Erich Doz. Dr. Friedrich Curtius. Papier. Price 18 marks. 1p. 21" with 17 illustrations. Leipzig: Georg Thieme, 1933.

No conclusion concerning the cause of multiple sclerosis is possible from the anatomic point of view. Curtius believes that many morphologic data point to a constitutional factor in this disease. A review of the cases reported in the literature shows that in 390 cases of multiple sclerosis reported there were 300 instances of organic nervous disease in the families of these patients and 183 instances of mental disease, 49 lacked exact data. Curtius investigated the families of 106 patients with multiple sclerosis but reports only on the families of 56 patients. Of 2,006 living relatives traced, 1,036 or 51.6 per cent, were examined. A control series of 56 families of fracture patients was used. It was found that nervous and mental diseases were more common in the relatives of patients with multiple sclerosis than in control groups in a ratio of 1.64 to 1. Furthermore, the closer the relation by blood the greater the incidence of these diseases. It is concluded that there is an abnormal genotype which is the deciding factor in the origin of multiple sclerosis. Curtius found what he called micro-heredodegenerations in the families of patients with multiple sclerosis. By this he meant the occurrence of hereditary signs of various sorts such as middle ear deafness, tumor (4 out of 56 families), tremor (3 out of 56 families), stuttering, abducens paralysis and anomalies of the abdominal reflexes. Furthermore the occurrence of psychopathic traits in the families of patients with multiple sclerosis far exceeds that of the control population. A study of patients with multiple sclerosis reveals the fact that many of them show constitutional abnormalities of various sorts. All these facts tend to support the view that the constitution of the patient with multiple sclerosis is abnormal and must be given greater consideration in the etiology and pathogenesis of the disease.

A Manual of Diseases of the Nose Throat and Ear By E B Gleason MD LL D, Professor of Otolaryngology, Medical-Chirurgical College Graduate School of Medicine University of Pennsylvania Seventh edition Cloth Price \$4.50 Pp 651 with 260 illustrations Philadelphia & London W B Saunders Company 1933

The repeated editions of this book testify to its worth. Within the limitations which the author sets for it, it succeeds remarkably well in its purpose. It is well bound and printed. There is a profusion of illustrations, for the most part clear and accurate. The general tone is conservative, and there is an astonishing amount of valuable information supplied within a small compass.

Medicolegal

Workmen's Compensation Acts Mental Deterioration and Death Due to Arteriosclerosis, Not Trauma—Spalding, a blacksmith, about 58 years old was found sitting in a dazed condition in a pit in which he had been working. He was able, however, to climb up the steps leading out of the pit and to take off his overalls. He was taken to Dr Miller's office, and after he was helped out of the car he walked without assistance to the office. Dr Miller made a casual examination in the course of which he found a bruise on the patient's back, in the right lumbar region, but he did not discover an injury to the head that, according to later evidence, was present. Spalding was taken home in a car and was cared for there by his family, without the aid of a physician. About a week or ten days later he called on Dr Miller but Dr Miller did not even then learn of the alleged injury to the head although Spalding's head was said to have been bandaged during his treatment at home.

Spalding who had been injured Jan 31 1925 returned to work within a week. He continued at work through the month of February or nearly so. Then he quit of his own accord, because he could not get his mind on his work. During the two and one-half to three years preceding his injury he had been a competent worker losing no time from sickness or otherwise. After he quit work, mental confusion and physical incoordination were shown in various ways, although as late as Jan 15 16 and 17, 1927 he took, temporarily the place of a regular blacksmith in the establishment where Spalding had been employed, doing his work although not as well as the regular blacksmith would have done it. Generally however he was nervous and agitated he would begin to talk on a subject and before he had finished he would wander off it to some other subject he would wander away from home, he stopped chewing tobacco because he had difficulty in spitting properly, he had difficulty in feeding himself, and various odd jobs some of which he had formerly done well he could not do at all. He grew progressively worse until his death Feb 26, 1928. The cause of death was certified as embolism of the brain. No autopsy was done. No roentgenogram was ever taken.

A claim was filed under the Illinois workmen's compensation act and although arbitrators made awards the industrial commission set them aside holding that Spalding had sustained no disability entitling him to compensation during his lifetime and that his death was not caused by the injury he received. The circuit court reversed the order of the commission and entered an award in favor of the claimant. From this judgment the employer appealed to the Supreme Court of Illinois.

On behalf of the claimant, medical witnesses testified that the injury was a contributing factor in Spalding's death. One witness testified that arteriosclerosis from which the employee seemed to have been suffering might have been a contributing factor but in his opinion it was not a natural inference that a disease caused the condition following the accident in view of the fact that the employee was well to all appearances before the accident and was able to do his work well. A serious result in the opinion of this witness might follow an injury to the head although no fracture resulted. A laceration of the brain might follow gradually causing the brain to deteriorate in relation to its former or natural condition. On behalf of the

employer, other medical witnesses testified that the injury was not a contributing factor to the death. One witness testified that the employee's condition was due to a hardening of the cerebral arteries. Another testified that if an injury is sufficient to produce an embolism, the embolism usually appears immediately, and that he would not expect an embolism to result from an injury occurring two or three years before the patient's death. In his opinion there was no connection between the injury and the death. Another witness testified that a man who had received a bruise on the back of his head from falling backward would not have had such a condition of sclerosis as the employee had in this case as a result of those injuries. If the injury was sufficient to cause a laceration of the brain tissue continued this witness, death would not have ensued after a period of three years from such an injury if the man was up and around during that time. Lacerations of the brain are immediate in their effect. This witness could not conceive of the injury received over the back of the head as producing a laceration, since the back of the head affords the greatest protection for the brain.

The burden is on the claimant, said the Supreme Court of Illinois, to prove that an injury sustained is the proximate result of an accident suffered in the course of and arising out of the injured person's employment. If there is a pre-existing disease compensation is allowable for all the consequences attributable to the injury in the acceleration or aggravation of the disease. The liability cannot rest on imagination, speculation or conjecture but must be based on facts established by a preponderance of the evidence. It cannot rest on a choice between two views equally compatible with the evidence. There was in the present case, continued the court, no serious conflict in the evidence about any fact in the case. There was no disagreement about the law. The solution of the question depends on the conclusion drawn from all the uncontradicted evidence concerning the facts and the divergent opinions of the expert witnesses. From a consideration of the testimony of all the witnesses, continued the court, the industrial commission would have been justified in finding that the employee was suffering from hardening of the arteries, which was the cause of the progressive decay of his mental and physical powers that this disorder was not and could not have been caused or lighted up or made worse by a fall or a blow, that the acts and symptoms shown by the evidence could not have been produced by the fall unless there had been a laceration of the brain or spinal tissue, of which there was no evidence, that the fall and consequent injury, if it had caused a laceration of the tissue of the brain or spinal cord, would have more serious immediate results, as unconsciousness and physical helplessness. There is ample evidence in the record to sustain the findings of the industrial commission, said the court, and unless the judgment of the commission is manifestly contrary to the weight of the evidence, the court has no authority to substitute its judgment, on the facts, for that of the commission. The action of the industrial commission disallowing an award was consequently affirmed.—*Rittler v Industrial Commission (Ill)*, 184 N E 654

Malpractice Failure to Discover Fracture of Radius, Inability of Plaintiff to Obtain Expert Witnesses—The plaintiff a minor, sustained injuries when he fell off a fence. The defendant was called to treat the injuries and discovered a fracture of the ulna of the left arm. He reduced the fracture and placed the arm in splints. In this action there was no complaint that the fracture of the ulna was not properly treated but the plaintiff contended that the defendant failed to discover a 'dislocation' of the radius either at the time of the accident or at a reasonable time thereafter. The jury rendered a verdict for the defendant and, when the trial court denied the plaintiff's motion for a new trial he appealed to the Supreme Court of Rhode Island.

After the defendant reduced the fracture of the ulna, he sent the plaintiff to a clinic to have a roentgenogram taken of the injured arm. This roentgenogram being unsatisfactory another was made. Neither revealed any injury to the radius. When the splints were removed the defendant discovered a condition which caused him to have a third roentgenogram taken and this revealed a fracture of the radius. A specialist in orthopedic surgery was consulted and an operation was performed.

by this specialist. The condition of the arm improved after the operation but at the time of the trial there was considerable limitation of motion in the elbow. In Rhode Island said the Supreme Court, the question as to whether a physician uses proper skill and diligence in treating an injury must be determined by the testimony of experts in medicine and surgery. Counsel for the plaintiff contended, however, that while this rule was correct when it was announced, it should now be modified. This contention was based, counsel stated on his experience in attempting to obtain expert medical testimony to support the charge of negligence on the part of the defendant. He stated that unless the rule be modified there is no possible way for any one who suffers injury at the hands of a negligent physician to recover his just damages. This statement, if true said the court, is a matter of grave concern to those charged with the administration of justice. Notwithstanding the experience of plaintiff's counsel the court was unconvinced that the ethical standards of the medical profession countenance a course so subversive of justice and so opposed to the duty which the profession owes to the public. We are not informed continued the court how far afield plaintiff's counsel went in his search for medical testimony. There might be a natural reluctance on the part of physicians practicing in the same locality to appear as experts against a fellow practitioner. We cannot believe the court said that there are not in the state of Rhode Island many well qualified physicians who would be willing to assist by their testimony a person who was a victim of malpractice. Furthermore the plaintiff's counsel might have had recourse to section 18 chapter 342 General Laws, 1923, where it is provided that "Any justice of the superior court may, in any cause, civil or criminal, on motion of any party therein, at any time before the trial thereof appoint one or more disinterested skilled persons, whether they be residents or nonresidents, to serve as expert witnesses therein." According to the medical testimony, the court concluded the defendant in his treatment of the injury, met the requirements as to skill and care as established in *Bigney v. Fischer*, 26 R. I. 402 59 A 72, where the court said "The implied contract of a physician or surgeon is not to cure—to restore a fractured limb to its natural perfectness," but to treat the case with that degree of diligence and skill which are ordinarily possessed by the average of the members of the profession in good standing, in similar localities regard being always had to the state of the medical profession at the time. And, if he do this, he discharges his full liability." All of the plaintiff's exceptions were overruled and the case remitted to the trial court for the entry of judgment on the verdict for the defendant—*Coleman v. McCarthy* (R. I.), 165 A 900.

Malpractice Joint Liability of Physicians Treating Patient Independently and at Different Times—The plaintiff had been treated, at different times by a number of physicians apparently for the same ailments. Failing to obtain the desired relief, he instituted a suit against these physicians, joining them all as defendants in one action. In his petition, the plaintiff alleged that he engaged the defendant-physicians in the county of their respective residences, where each treated his ailments by virtue of separate and independent engagements, and that their separate treatments afforded him no relief. In an effort to state a joint cause of action against the defendants, the petition further alleged that their separate and successive treatments were not successful, that the plaintiff was not cured of his ailments, and that this was caused directly by the concurrent negligence of the several physicians. The case was dismissed by the trial court, and the plaintiff appealed to the Court of Appeals of Kentucky.

It is very plain, said the Court of Appeals, that the petition states against each of the physicians a distinct and separate cause of action occurring in the several counties of the residences of the physicians. The facts thus appearing, the allegation that the plaintiff's injury was caused directly by the concurrent negligence of the several physicians does not relieve the case of the fact that the pleading states an independent separate and distinct cause of action against each of the named physicians. If the diagnosis and treatment by any one of them was negligently done, continued the court, or was such as to

constitute malpractice, the injury therefrom was complete before the services of the next employed physician were engaged or his services were rendered. Neither the engagements nor the services of the physicians were in any sense concurrent, said the court. The plaintiff contended, however, that although the physicians who treated him acted independently, yet each of them was guilty of negligence at the time of the performance of his separate services and that it was not essential for the maintenance of his joint action against them to allege that they were engaged in a common enterprise or sustained any relation whatever between themselves. The correct rule said the court as stated by Sherman and Redfield on Negligence (ed. 4) sec. 122 is as follows:

Persons who cooperate in an act directly causing injury are jointly liable for its consequences if they acted in concert or united in causing a single injury even though acting independently of each other.

Since therefore, the defendant-physicians did not act in concert nor unite in causing a single injury, the court concluded, the plaintiff had no joint cause of action against them.

Furthermore a physician is not an insurer and is liable only where negligence is the proximate cause of the patient's injury. Negligence will not be inferred from poor results or failure to effect a cure. A physician is liable to his patient only for an injury due to want of requisite knowledge and skill or to failure to use reasonable care and diligence in diagnosis or treatment. The import of these elementary principles continued the court is that when physicians act independently of each other in diagnosing and treating a patient, during distinct and different periods of time, each is liable for his own wrong or negligence but not for the negligence of the other, even though neither of them effects a cure of the patient's ailment. Conceding that the failure of the defendant physicians to effect relief was concurrent such concurrent failure cannot and does not create a joint cause of action against them, simply because none of them cured the patient or achieved the results desired or expected. Finding no error prejudicial to the substantial rights of the plaintiff the Court of Appeals affirmed the judgment of the trial court, dismissing the action—*Rose v. Sprague* (Ky.), 59 S. W. 2d 374.

Liability of Wrongdoer for Malpractice of Physician Who Treats Original Injury—Where a person, says the supreme court, Schoharie county, N. Y., injured through the negligence of another, exercises reasonable care in selecting a physician and his injuries are thereafter aggravated by the malpractice of the physician the negligence of the wrongdoer in causing the original injury is in law regarded as the proximate cause of the damages flowing from the physician's malpractice, and the original wrongdoer is liable therefor. Furthermore, a release by an injured person of the tortfeasor responsible for the injury prevents an action by such injured person against a physician for the negligent treatment of the injury—*Milks v. McLeer* (N. Y.) 263 N. Y. S. 592.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- The Premature Infant Study of Effects of Atmospheric Conditions on Growth and on Development K D Blackfan and C P Yaglou assisted by Katherine MacKenzie Wyman Boston—p 1175

Treatment of Grip in Children—Petranyi states that his own observations and those of others disclosed that the medicine administered was most effective (1) when it contained amidopyrine or derivatives of amidopyrine and (2) when larger doses than usual for babies and young children were given. This experience induced him to administer amidopyrine in unadulterated form in the following dosage day and night until the temperature reached normal from birth to 1 month of age 0.05 Gm, from 3 to 6 months 0.1 Gm from 6 to 12 months, 0.15 Gm and from 2 to 5 years 0.2 Gm. As soon as the temperature had fallen below 37 C (98.6 F) and had remained at this point for at least half a day, the intervals between the doses were lengthened to three hours, and if fever remained absent, to four hours later it was sufficient to administer the amidopyrine three times a day. If the temperature again rose, the intervals between the doses were decreased, this variation in interval continuing as long as necessary. The amidopyrine was prescribed in a 3 to 4 per cent solution, to be taken in a concentrated syrup. By this means an effective concentration of amidopyrine in the organism was reached and maintained. To stop the medicine too soon or too suddenly is an error; the diminishing of the concentration of amidopyrine demands great care or the drug does not have its full effect. The author tried the treatment in more than 100 cases. The most satisfying results were obtained among patients who showed sudden and severe symptoms high fever and occasional delirium. In these patients after the introduction of the treatment the fever generally diminished gradually in from twelve to twenty-four hours, in most cases the great exhaustion and weakness as well as occasional delirium were checked. Most of the good results are obtained in cases in which treatment is given immediately.

Treatment of Congenital Syphilis with Acetarsone—Traisman used acetarsone, administered by mouth in the treat-

ment of fifty-four patients having congenital syphilis. The first week a dosage of 0.005 Gm per kilogram of body weight was administered daily, the second week, 0.01 Gm, the third week, 0.015 Gm, and the fourth week, 0.02 Gm. During the following five weeks the dosage was 0.02 Gm. A rest period of six weeks followed the treatment. The amount of the drug ordered was dissolved in water and given a half hour before feedings. In the group of infants under 1 year of age, 71 per cent showed a reversal of the Wassermann and Kahn reactions. In the children between the ages of 1 and 6 years, the Wassermann reaction became negative in 55 per cent and the Kahn reaction in 33 per cent. In the group between 6 and 12 years of age, the Wassermann reaction became negative in 47 per cent and the Kahn reaction in 19 per cent. In the forty patients completing a second course of acetarsone therapy the Wassermann reaction became negative in 50 per cent and the Kahn reaction in 33 per cent. The clinical symptoms improved rapidly and the physical development showed marked improvement. No serious urinary changes were noted, except in one child who developed a severe arsenical dermatitis and died on the seventeenth day after the onset of symptoms. The blood of the younger infants showing a secondary anemia improved rapidly with acetarsone therapy. Eosinophilia was a frequent observation. Lesions of the bones showed rapid healing in all cases, both clinically and roentgenologically after one course of treatment. Examination of the spinal fluid gave negative results in the thirty-one patients examined.

Auriculosystolic Murmur—Wolferth and his associates heard an auriculosystolic murmur over the tricuspid area in two cases of cardiac infarction during convalescence. In one case it was first discovered on the fifteenth day and disappeared on the twenty-third. In the other, it developed on the fifth day and disappeared on the twenty-seventh. In both instances the infarct was probably located in the anterior surface of the left ventricle. In one, the behavior of the sound was observed

during partial heart block and during a paroxysm of auricular fibrillation. The authors' evidence concerning the cause of this murmur is as follows: 1. The place at which it was best heard suggests that it is dependent on some disturbance in the neighborhood of the tricuspid valve. 2. It resembled the presystolic murmur of mitral stenosis with respect to its relation to auricular activity. During normal rhythm and during partial heart block it followed the P wave of the electrocardiogram. During auricular fibrillation it became more difficult to hear; it began in early diastole shortly after the second sound and was audible in the presystolic period. 3. The two cases in which this murmur appeared were probably instances of occlusion of the left anterior descending coronary artery with infarction of the anterior surface of the left ventricle. Neither of them came to necropsy, but the electrocardiographic evidence of location was quite definite. 4. The authors examined a number of pathologic specimens of hearts with anterior infarction to determine whether any structural change could be found that might account for this murmur. A mural thrombus lying beneath one of the tricuspid leaflets might be able to produce such a murmur, but none of the specimens of anterior infarction had a thrombus in this location. Many showed a thinning of the anterior part of the interventricular septum and a bulging of this structure into the right ventricle. Edema of the tissues in and near the infarct was quite constant. One specimen with a posterior infarction from occlusion of the right coronary artery, showed a thrombus lying beneath the posterior leaflet of the tricuspid valve. The authors conclude that this murmur is probably related to convalescence from acute coronary occlusion and that it seems to be produced by the flow of the blood from the right auricle to the right ventricle.

Pneumoperitoneum Incidental to Artificial Pneumothorax.—Banai presents two cases of direct pneumoperitoneum. It occurs when the pneumothorax needle is inserted below instead of above the diaphragm. His manometer readings indicate that the subdiaphragmatic intra-abdominal pressure is negative and that it oscillates parallel with changes of the intrapleural pressure. He reports two cases of indirect pneumoperitoneum and concludes, from the study of the symptoms and roentgenologic observations that in these cases the air found its way from an established pneumothorax into the peritoneal cavity along the structures passing through the diaphragm. The best means for establishing the diagnosis is the roentgenogram taken in the upright position. Immediate symptomatic relief can be obtained by elevating the foot of the bed thus shifting the air from below the diaphragm to the pelvis. Proper orientation as to the position of the diaphragm in relation to the site of injection and avoiding the forcing of air under high pressure will aid in preventing the occurrence of accidental pneumoperitoneum.

Treatment of Cancerous Neck Lymph Nodes.—In every case of true squamous carcinoma or adenocarcinoma arising on the lip, mouth, pharynx or anywhere in the lining of the cheek Blair and Brown attempt to eliminate the possibly infected lymph nodes preferably without waiting for their metastatic infection to become evident. Whenever it appears practical the primary growth is controlled before the attempt is made to deal radically with the lymph nodes but radiation is usually given to the areas of the neck in the hope of retarding the development of metastases while waiting the most desirable time to do the operation. In certain advanced growths it may be necessary to destroy the primary growth and remove the related lymph nodes at one sitting. For growths confined to one side of the midline and situated anterior to the foramen cecum or the posterior tracheal pillar the removal of the lymph nodes is limited to that side of the neck unless the other side becomes involved. The most effective way of preventing or eliminating infection of these areas of the neck is by dissection that removes the entire lymph bearing tissues. Inoperable invasion of lymph nodes can frequently be controlled by direct implantation of radon or radium by intensive roentgen therapy after the skin that covers the growth is turned back or by a combination of the two. In the authors' cases of dissection of the neck in which masses of nodes were not fixed directly to the carotid artery and had not eroded the mandible there is but one recorded recurrence in the neck, 2 per cent. In twenty-one of these cases the nodes were found to be positively cancerous and ten patients are known to be well from five to fourteen years after operation. In twenty-six the nodes were reported microscopically negative and eighteen are known to be well from five to eighteen years after operation. In the series of seventy cases of combined operation, there were sixteen cures of five to eighteen years. In twenty-nine the nodes were apparently negative with six cures while forty-one were definitely positive with ten cures. After destruction of squamous cell growths occurring in the lip or mouth below the level of the oral slit whether by radium, cautery or removal and for those occurring in any part of the cheek the authors perform a radical regional block removal of the lymph nodes either at the primary or at a secondary operation if the patient will submit and if the operation looks feasible. For squamous cell lesions above the level of the oral slit with the exception of the lining of the cheek they usually do not urge the removal of the lymph nodes unless cancer-like nodes are present at the time of the treatment of the primary lesion. They treated adenocarcinomas and endotheliomas along the same lines but for the lymphosarcomas and all the primary malignant conditions of the lymph nodes, no matter how named they depend on radiation after the diagnosis is established. All these patients seem to die within four years at the outside regardless of the kind of treatment.

Massive Hemorrhage from Duodenal Ulcer.—From a review of 1804 cases, Allen and Benedict believe that patients suffering from duodenal ulcer who have recovered from a severe hemorrhage should be subjected to surgery in a quiescent state as the possibility of a persistence of symptoms is great and the incidence of future episodes of severe hemorrhage is about

40 per cent. Spontaneous recovery is less likely with increasing age. About one third of all their duodenal ulcer patients requiring hospitalization have gross bleeding. More than 3 per cent died of hemorrhage. The mortality in sudden massive bleeding from duodenal ulcer was 14.5 per cent, regardless of treatment. Age seems to be the most striking single factor in determining the possibility of spontaneous recovery. Death from hemorrhage occurs rarely in patients less than 50. In persons with acute massive hemorrhage beyond middle age and who do not show early evidence of a complete cessation of bleeding, immediate surgery should be contemplated. Matched citrated blood should be kept in the refrigerator, or a donor should stay at the hospital. Transfusion should be done quickly if there is a second collapse and before the systolic pressure falls below 70 mm of mercury. If there is a rapid loss of the benefits of this transfusion, a large transfusion should be given and the patient immediately operated on. The authors describe an operation for patients who continue to bleed owing to a large open vessel situated in an eroded area in the pancreas. In order to control the loss of blood during the operative procedure, the lower third of the stomach down to the ulcer is transected and freed. Then the distal clamp is removed and the anterior wall of the lower segment is opened. The bleeding point is controlled by a finger or tamponade and the resection continued without serious loss of blood. The vessels entering the edge of the ulcer are intercepted as the inflammatory tissue is cut across. When the hemorrhage is controlled, a retractor is placed in the duodenum and the level of the ampulla of Vater is ascertained. If there is room to free the duodenum beyond the bed of the ulcer and to allow a satisfactory turn-in, the operation is easily completed. If there is doubt concerning this or if the erosion in the pancreas is large and sufficiently deep to have opened an accessory pancreatic duct, a modified procedure is done. A part of the elevated distal portion of the stomach is eliminated, leaving a sufficient amount of the prepyloric region for easy suture. The duodenum and the stump of the stomach are sutured in such a way as to enclose the ulcerated area in the pancreas. If one is anxious to destroy the remaining activating area in the antrum and the patient's condition permits the mucosa is removed from this region as suggested by Bancroft before the closure is made. Anastomosis between the stomach and the intestine may be made by the Polya or second method of Billroth.

Hypothalamus and Temperature Control—Bazett and his associates made a histologic study of the brain stems of cats which were submitted to anterior decerebrations. The animals had the capacity of reacting to cold and of regulating their own body temperature at a normal level (and probably of developing fever) in the absence of the corpus striatum and the thalamus, which were not therefore essential. The presence or absence of temperature control appeared to be associated with the preservation of the hypothalamus just cephalic to the mammillary bodies, the area included the nuclei surrounding the walls of the third ventricle and the infundibular nuclei. Such animals did not however show a normal hyperpnea when exposed to excessive heat.

Megalocephaly with Glioblastomatosis of Brain Stem and Cerebellum—Weil reports a case of megalocephaly which, like Marburg's case, presented a combination of interstitial hyperplasia with diffuse glioblastomatosis and interstitial

hypertrophy, demonstrating the intimate relationship between these processes. This occurred in a boy, aged 7, whose mental development had been normal up to the sixth year and whose brain weighed 1,856 Gm. Hypertrophy of the cerebral hemispheres was combined with diffuse glioblastomatosis of the brain stem and the cerebellum. The author believes that a congenital, familial maldevelopment is suggested by the megalencephaly of the still living brother and by the congenital underdevelopment of the precentral area, the skeletal musculature and the chromaffin tissue of the medulla of the suprarenals.

Branchial Fistula—Klemert reports a case of complete branchiogenic fistula with external and internal openings and also the cases of the six patients presenting this condition who were operated on at the Massachusetts General Hospital and in the Massachusetts Eye and Ear Infirmary during the years 1926 and 1931. From a study of these cases the author concludes that the true fistula is a complete tract which passes from an external opening just above the clavicle along the border of the sternocleidomastoid muscle and opens into the throat. It is present in the neck from birth. Microscopic examination shows that this fistulous tract is lined with squamous epithelium. These distinctive diagnostic points are all found in the case reported here.

Hyperpyrexia in Mercurial Poisoning—Billman reports a severe case of mercurial poisoning in which the kidneys were congested to the point of complete inactivity and the mucous membranes of the gastrointestinal tract were necrotic from the mouth to the rectum, with retention of all body fluids. It was obvious that measures should be utilized to carry on the function of the impaired organs. To attempt the precipitation of the mercury into an inert or insoluble form would be futile while the whipping of a nonfunctioning kidney into action was out of the question. Fischer's solution by rectal drip was used for the anuria and preeclamptic state. The kidneys were of momentous concern. Marked diaphoresis would compensate for the dysfunction of the kidneys and a superficial capillary dilatation would relieve the congestion. Both effects might be obtained by hyperpyrexia, and with this line of logic this treatment was initiated six days after the ingestion of the poison and when ordinary measures were of no benefit. Treatment was begun, one hour being allowed for the peak tem-

perature of 101 F to be reached, at which time the current was turned off. The temperature was allowed to rise forty-five minutes, when the blankets were removed and a few drops of urine were obtained by catheter. The next day fever therapy was repeated. The current was turned off at 101.2 F. The following day the patient was feeling better and had passed some urine during the night. Owing to the patient's dislike of diathermy and the fact that a slight improvement was noticed, it was decided to defer treatment to a later date. This was not necessary, as she made a steady improvement until she was discharged from the hospital.

Hemiplegia Due to Tuberculosis of the Corpus Callosum—Montgomery reports the case of a man, aged 69 with bilateral cataracts, who was admitted to the hospital complaining of dizziness, headache and weakness of the left side and showing evidence of a progressive left hemiparesis increased spinal fluid pressure presence of globulin and an average of 35 mononuclears per cubic millimeter. The duration of his illness was fifty-two days, the course of the disease was practically afebrile, the blood pressure remained within normal limits and there was only a moderate degree of leukocytosis on admission. The clinical diagnosis was encephalitis, right cerebral thrombosis, left hemiplegia, bilateral cataracts, and hypostatic congestion of the lungs. At postmortem examination the only gross abnormality found was edema and congestion of the lungs and a marked thickening of the corpus callosum. This portion of the brain was soft and friable and presented a necrotic appearance suggesting a possible brain tumor. Microscopic sections taken from the different organs showed 1 Recent miliary tubercles in the lower lobes of both lungs, no primary focus of tuberculous infection was found in either lung. 2 Recent miliary tubercles in both lobes of the liver. 3 No evidence of tuberculosis in the spinal cord or meninges. Sections taken from the corpus callosum on a plane with the Rolandic cortex showed a diffuse lesion in which the structure of the brain was entirely replaced by an irregular cellular mass, in which the blood vessels were markedly engorged and tortuous. Many of these vessels were thrombosed. There were several areas of degeneration scattered throughout this region, and about these degenerated areas there were numerous polymorphonuclear cells, lymphocytes and large mononuclear cells. Throughout the whole lesion the type of the cells varied. There were numerous large eosinophil cells with pigmented nuclei lymphocytes, large rounded mononuclear cells and a dense filled network made up of branching cells with elongated nuclei between which there was a good deal of fibrillar material. In some of the necrotic areas there was frank hemorrhage. In other fields there were some small necrotic areas surrounded by cellular condensation arranged in a radial fashion suggesting a tubercle. The author is convinced that he was dealing with a tuberculoma of the corpus callosum, also that this lesion was definitely older than the miliary tubercles found in the lungs and liver and that the latter were due to an infection of the blood stream.

Roentgenography in Gallbladder Disease—Hess describes a modified intravenous method for the diagnosis of disease of

the gallbladder. The method is effective and practically without reaction, and the result is certain and satisfactory. Sterile physiologic solution of sodium chloride is placed in a large buret suspended from 18 to 24 inches above the site of injection. This is connected to a large-bore hypodermic needle by means of a small-bore rubber tube provided with a stopcock or clamp. About 3 or 4 inches proximal to the needle, a small section of glass tubing is introduced as a window. The needle of the apparatus is introduced into the median basilic vein and the saline solution is allowed to flow until it is quite evident that the point of the needle is within the lumen of the vein and that no extravasation has occurred and that the saline solution flows freely. The solution of tetraiodophthalein sodium has already been prepared by dissolving the necessary amount in about 20 cc of glass distilled water and this is then placed in a large syringe. The surface of the rubber tubing immediately distal to the small glass window is sterilized with alcohol and the injection of the solution of tetraiodophthalein sodium is made directly into the rubber tube. It will then be found impossible to inject faster than the saline solution can flow by gravity through the needle in the vein and any backflow is seen at once by the colored solution of tetraiodophthalein sodium appearing at the window. When the desired total quantity has been introduced, the needle of the syringe is withdrawn from the rubber tubing and the saline solution is allowed to continue to flow from the buret. By this means ample dilution is obtained, there is no possibility of extravasation into the tissues the vein at the site of injection is washed clear of the solution of tetraiodophthalein sodium by means of the saline solution and a slow injection is assured. The first series of roentgenograms is made about fourteen hours after the administration of the dye. A second series is made after a meal of cereal and cream or toast, with plenty of butter and tea in order to observe contraction and concentration of the gallbladder. A third series of roentgenograms is made four hours later in the event satisfactory shadows were not obtained on the first series, further roentgenograms are made with a changed angle of the central ray and the penetration slightly varied until it is shown definitely that no satisfactory gallbladder shadow can be obtained.

Method for Separating Pressor and Oxytocic Substances from Posterior Lobe of Pituitary—Stehle outlines a procedure for separating pressor and oxytocic substances

from the posterior lobe of the pituitary gland in which inert material is first removed by two successive precipitations through the use of (1) alcohol and (2) barium hydroxide, ferric sulphate and colloidal iron. The concentrate obtained is dissolved in dilute alcohol and the solution is fractionally precipitated with ethyl acetate. This results in a partial separation. The fractions are further purified by a step which utilizes the different distribution of the substances between the two phases of a water-alcohol-ethyl acetate system, the pressor substance concentrating in the aqueous phase and the oxytocic substance in the ethyl acetate phase. The author presents some observations on the chemical properties and pharmacologic actions of the fractions.

Treatment of Bronchopulmonary Suppuration with Neoarsphenamine—Spector investigated the value of small doses of neoarsphenamine in the treatment of three patients suffering from acute suppuration of the lungs, who failed to show improvement and were definitely worse after a reasonable time of treatment with the usual conservative measures. There was a drop in the temperature within twenty-four hours, and the patients improved steadily to complete recovery. In order to confirm these results the author treated twenty-two additional cases of acute and chronic suppuration of the lungs, in the lungs of which sputum spirochetes were found. The initial dose in an adult was usually 0.15 Gm and was repeated every four days until clinical improvement was marked and the sputum became negative for anaerobic organisms. At times the dose was increased to 0.3 Gm, at other times it was decreased to 0.1 Gm, and at other times to 0.05 Gm. The number of injections given to an individual patient varied from one in a case of acute putrid bronchitis to fourteen in a case of tuberculosis complicated by fusospirochetal infection. The total amount of the drug used in each case varied from 0.15 Gm in the former to 27 Gm in the latter case. The best results were obtained when the treatment was started early. Generally it was noticed that the very sick patients responded to the treatment better if smaller doses were used. The author concludes that the possible action of small doses of neoarsphenamine in the treatment of fusospirochetosis is that arsphenamine through its specific spirillicidal action kills the spirochetes and through its nonspecific tonic action stimulates the formation of agglutinins and lysins which in turn destroy the other members of the symbiotic group.

Method of Recording Diuresis—Gower and Van de Erve outline a method of recording diuresis which consists of collecting the urine through a retention catheter into a cylinder containing a float the rise of which is recorded by means of a suitable lever system and writing point on a smoked drum moving about 25 cm per hour. At the top of the excursion the cylinder is automatically emptied returning the writing point to the base line for another trip. The method allows of considerable variation and refinement. The authors arrange

ment consists of three upright parallel cylinders with communication at their bases, one for receiving the urine, one for operating the float and the third for emptying the apparatus intermittently by siphon. Each excursion represents approximately 35 cc of urine.

Actions of Dinitrophenol—Tainter and Cutting observed that repeated administration by different routes, of alphanitrophenol (1-2-4) to dogs at intervals of three or more days does not result in tolerance within a period of from two to three months. Studies of the urine, van den Bergh tests and icteric indexes all failed to reveal any evidence of a toxic action during such administrations. There were no significant pathologic alterations in the important organs, aside from some possible injury to the spleen. The fatal doses per kilogram for 50 per cent mortality were: rats 25 mg subcutaneously, dogs, 22 mg subcutaneously, 20 mg intramuscularly, 30 mg intravenously and between 20 and 30 mg orally, rabbits, 30 mg subcutaneously, and pigeons, 7 mg intramuscularly. Excised intestinal strips from rabbits showed response to dinitrophenol in high concentrations only, which depressed the muscle directly. Dinitrophenol may increase the rate and depth of respiration in rabbits previously depressed by toxic doses of morphine, chloral, alcohol or barbital, as does caffeine. The animals may still die, in spite of maintenance of adequate pulmonary ventilation. When the full respiratory stimulation of dinitrophenol has developed morphine promptly reduces it to normal. Dinitrophenol was not successful in preventing death from just fatal doses of sodium barbital. Arterenal, sodium gluconate, dextrose and insulin, monoiodoacetic acid, quinine and salicylate were found ineffective antidotes in rats. The administration of physiologic solution of sodium chloride or cooling by means of tepid baths exerted a partial antidotal (antipyretic and antimortal) effect. Dinitrophenol failed to prevent death from sodium cyanide in pigeons under conditions in which methylene blue is effective and is of no permanent value as an antidote in cyanide poisoning. No antiseptic action was found against *Bacillus coli* or streptococci *in vitro* or against trypanosomiasis in rats. Alphanitrophenol (1-2-4) is more effective in producing fever in pigeons, as far as degree of fever and regularity of response are concerned than are metamonitrophenol and paramonitrophenol. Betadinitrophenol or gammadinitrophenol or trinitrophenol. The authors state that these results taken together with those of their previous reports establish the basis for the use of dinitrophenol in physiologic and pharmacologic experimentation for increasing metabolism and body temperature. They also indicate the possibility of applying this drug in the treatment of various clinical conditions in which an increase in the basal metabolism or a fever might be of benefit. Properly conducted clinical tests are imperative before any clinical applications could be considered.

Action of Cocaine on Intestine—The experiments of Bernheim demonstrate that cocaine in concentrations of from 0.1 to 0.2 per cent causes relaxation of the ileum of the guinea-pig contracted by histamine or pilocarpine. The extent of the

relaxation is a function of the amount of cocaine added and the amount of histamine or pilocarpine. Cocaine causes relaxation of the ileum after contraction by barium. The action of nicotine and cocaine is additive. He concludes that cocaine, like nicotine and atropine, acts both on smooth muscle directly and on the parasympathetic endings.

*Postural Wedge Compression of the Thorax Aid to Maximal Collapse Prevention of Scoliosis and Visualization of Possible Residual Cavity After Thoracoplasty J. D. Bisgard Ann Arbor, Mich.—p. 99

Experimental Pulmonary Aspergillosis with *Aspergillus Niger*—Bethune and Moffatt grew a fungus identified as *Aspergillus niger* from the sputum of a patient having pulmonary tuberculosis with bilateral cavitation, Gaffky V. The spores of this fungus were abundant in the patient's sputum and were grown repeatedly on any ordinary culture mediums. The fungus produced, by inhalation experiments, a chronic pulmonary granulomatous lesion, regressive in nature. It appeared to produce little or no fibrosis in guinea-pigs, rats and rabbits during an observation period of from 7 to 540 days. The spores when inhaled were rapidly engulfed by alveolar phagocytes and became broken up within these cells up to a period of fifty days. By this time the phagocytes had been able to fragment them. No cultures from the lungs were obtained after this period of time. No positive cultures were obtained from the trachea or bronchi after inhalation. Attempts to produce ulceration in the external ear failed. No evidence was found to favor the theory that *Aspergillus niger* may be responsible for the extensive fibrosis and nodular calcification as seen in some roentgenograms of human beings. To produce such fibrosis and calcification one would imagine that the original lesion if caused by the fungus, must have been extremely widespread and of a seriously debilitating nature and produced by the inhalation of large amounts of spores. The fate of the patient is unknown as he left the hospital three weeks after the operation and returned to Nova Scotia. No iodine medication was advised in view of the coexisting pulmonary tuberculosis.

Postural Wedge Compression of the Thorax—Bisgard states that postural wedge compression designates a procedure which applies the simple mechanical principle of leverage to the thorax for the purposes of gaining maximal compression of the thoracic wall after thoracoplasty and of preventing pleural and thoracoplasty scoliosis. The thoracic wall and spine are levered over a fulcrum with the patient lying on the diseased or operated side over a soft compression wedge, such as a rolled pillow. Much of the body weight is suspended on this wedge and exerts not only great localized pressure on the thoracic wall but also a bending force on the spine. The author recommends postural wedge compression during the early plastic period of readjustment of the thoracic wall and spine after thoracoplasty for the following purposes: 1 To mold the thoracic wall so that maximal pulmonary compression will be obtained until the maintenance of compression is assured by costal regeneration and fibrosis. 2 To prevent or correct scoliosis until costal regeneration, scar tissue formation and muscle reinsertion compensate for the spinal imbalance produced by thoracoplasty. 3 To aid in increasing roentgenologic visualization of the collapsed lung after thoracoplasty so that the presence or absence of an uncollapsed cavity in its mesial portion may be determined with greater accuracy to the end that collapse therapy may be more precisely regulated. 4 For the prevention and correction of pleural scoliosis.

*Anatomic Considerations in Radical Phrenic Excision and Scaleneotomy S. A. Thompson New York—p. 1105

Treatment of Undescended Testicles by Injection of Prolan—Goldman and Stern applied Engle's work on monkeys to human beings, that is, the treatment of undescended testicles by the injection of hormones obtained from the urine of pregnant women. They report two cases in which the anterior pituitary-like principle was used. The results obtained were encouraging. Not only was there a descent of the testicles in both of these cases, but there was an increase in the size of the testicles and a definite change in the secondary sexual characteristics. By analogy with Engle's work on monkeys, it seems likely that the increase in the size of the testicle was due to a hypertrophy of the interstitial tissue of the testicle and that the change in the secondary sexual characteristics was a result of the increase in the interstitial gland substance, with an ensuing increase in the male sex hormone.

Acetylsalicylic Acid Test to Determine the Advisability of Removal of Foci in Rheumatic Conditions—Wolf gives any patient complaining of a rheumatic condition from 10 to 15 grains (0.65 to 1 Gm.) of acetylsalicylic acid. If the pain is not relieved within an hour, the extraction of a tooth or a tonsillectomy is not advised, no matter what the oral

condition may be. This does not mean that abscessed teeth should not be extracted as a positive danger, but the patient in such cases should be told that relief of his pain is doubtful. Many physicians advocate the extraction of devitalized teeth without visible pathologic signs as a routine procedure in all cases of arthritis. It is well known, however, that these extractions often prove futile. The author does not advocate an extraction if the patient does not respond to salicylates. If he does, and if a number of teeth are devitalized or show improper fillings of the root without abscesses or rarefactions, he advises the removal of the fillings of the roots and the bacteriologic examination of the roots.

Radical Phrenic Exeresis and Scalenotomy—Thompson presents a technic for radical phrenic exeresis and scalenotomy based on anatomy. A horizontal incision is made approximately 2 cm above the clavicle. It begins over the lateral border of the clavicular head of the sternomastoid muscle, extends laterally for 2 or 3 cm and ends medial to the external jugular vein. The incision is carried to the deep cervical fascia, which is divided by blunt dissection. The omohyoid muscle should be retracted upward. The thin covering of the fat pad is opened and the fat is retracted from the operative field. This exposes the thin prevertebral fascia covering the scalenus anticus and medius muscles, the brachial plexus and phrenic nerve. Whenever possible, the phrenic nerve is found before dividing the prevertebral fascia to avoid its being retracted along with the edges of the fascia. The fascia is divided and a search for accessory roots is made. As the accessory nerve may join the phrenic nerve below the level of the clavicle it is better to divide the nerve to the subclavius even though no accessory fibers are apparent. Roots from the cervical nerves the hypoglossal and the cervical sympathetic should be divided as close to the main stem as possible. The main stem is then cut high up and the distal end is slowly pulled upward, by wrapping it round the forceps or reapplying the forceps at a distance of from 1 to 2 cm. If traction is applied slowly and easily, the entire length of the phrenic nerve with its diaphragm filaments may be removed. There is a distinct thud when the nerve separates from its attachments. Even when pericardial or mediastinal adhesions exist more than 12 cm of the nerve can be avulsed. The traction is somewhat painful but should not be hurried. The cardiac impulse may be felt while applying traction on the nerve if mediastinal adhesions are present. The respiratory tug may also be felt. After traction is applied any remaining accessory fibers may be severed as they appear in the incision. When the scalenus muscles are to be severed this can be done at the same time and the steps of the operation are identical up to this point, with the exception of the incision which is carried laterally 2 or 3 cm more. The external jugular vein is dissected and retracted. The scalenus muscles are exposed elevated and severed near their attachments. The scalenus anticus muscle must be severed below the level of the sixth cervical vertebra. Extreme caution must be taken in cutting this muscle not to wound the pleura or subclavian artery posteriorly. The brachial plexus may be retracted outward or downward and the muscle severed care being taken not to wound the pleura. The scalenus posticus may be severed at the same level as the medius. Following scalenotomy the first and second ribs have a tendency to sag and the first rib drops away from the subclavian vein and artery. For this reason when scalenotomy has been done as a preliminary to thoracoplasty a much greater length of the first rib may be removed. The operation is performed under infiltration anesthesia by the use of from 10 to 15 cc of a 0.5 per cent solution of procaine hydrochloride.

Gram-Positive Forms of Mycobacterium Lepae—Not being aware of any previous work on the subject, Rodriguez and his associates attempted to demonstrate the presence of non-acid-fast forms of Mycobacterium leprae in leprotic lesions of the skin which were persistently negative for the acid-fast organisms. After smears were prepared from the cutaneous lesions in the ordinary manner and fixed by heat Muc's modification of Gram's stain was followed, step by step. They found that by the use of this method it is possible to demonstrate the presence of gram-positive forms of M. leprae in a considerable proportion of leprotic lesions which do not contain acid-fast bacilli. That many of these non-acid-fast bacilli are not merely degenerated forms may be judged from the fact that they are numerous in many cases of so called closed or incipient cases of leprosy that have not undergone treatment.

Irradiation in Treatment of Osteogenic Sarcoma—Coley states that the routine treatment of early operable cases of osteogenic sarcoma by irradiation should be abandoned. Preliminary or preoperative irradiation is without justification. The author's present data are insufficient to permit a positive opinion as to the value of postoperative irradiation after amputation but he believes that osteogenic sarcoma is so radio-resistant that it is doubtful whether irradiation would control pulmonary metastasis that might have been present but undetected at the time of the amputation. There is a type of osteogenic sarcoma known as periosteal fibrosarcoma characterized by little involvement of the bone itself and of a much lower malignant degree than is the ordinary osteogenic sarcoma that he has found most responsive to treatment. Three patients with this type of sarcoma have remained well for three years and one for nearly two years one was treated by irradiation alone and three by irradiation combined with Coley's toxins. The

author is of the belief that conservative treatment is justified in this type of bone sarcoma, notwithstanding statements that no case has been found permanently cured with anything short of amputation. For all other types of operable osteogenic sarcoma of the long bones he believes that an amputation as soon as the diagnosis has been made, followed by prolonged treatment with Coley's toxins, is the method of choice. The endothelial myeloma type of bone sarcoma is highly sensitive to both irradiation and Coley's toxins. Under irradiation alone this result has seldom proved to be lasting. In cases of operable endothelial myeloma of the long bones conservative treatment, local irradiation and Coley's toxins should be tried for from four to six weeks before advising amputation. Irradiation is of considerable value in many cases of inoperable osteogenic sarcoma because of the retarding effect on the growth of the tumor and the relief of pain. In certain cases of far-advanced inoperable osteogenic sarcoma that had best be treated without irradiation or toxins, morphine is the method of choice.

Leukemia Involving Intestinal Tract—Mend points out that comparisons of the gastrointestinal manifestations of leukemia, leukemias, lymphogranulomatosis and lymphosarcomatosis show a marked clinical, pathologic and hematologic similarity. None of the diagnostic features of these conditions are characteristic. Because these conditions usually cannot be differentiated from carcinoma of the intestinal tract they assume an important differential diagnostic significance. Accurate diagnosis depends principally on a careful correlation of the clinical, roentgen and laboratory observations. The combination of surgical treatment and roentgenotherapy has been shown to offer the greatest therapeutic benefit in the treatment of lymphoblastomas in general. Intestinal resection in a small series of cases, has shown no immediate operative mortality. Gastric resection, in two relatively small series of cases has shown an immediate operative mortality of approximately 15 per cent. The average duration of life after gastro intestinal resection has been approximately one year, however, a considerable number of five-year cures have been reported. Isolated cases are reported of survival as long as eight, nine and fifteen years after operation without recurrences.

Tetany Calcipexicus of the New-Born Infant—Blossom and Nicholas report two cases of spasmophilia of the new-born infant with an extremely high diffusible calcium and an apparently low concentration of ionizable calcium in the blood serum of one infant. Introduction of more calcium ions reduced the diffusible calcium concentration, increased the total calcium concentration and resulted in the complete recovery of the infants neuromuscular irritability. The authors call attention to the possible difference in the production of this type of

spasmophilia occurring in new born infants who had symptoms similar to classic tetany and to that producing tetany in older infants. They believe that there is a substance present in the blood serum of the mother and infant preventing ionization of the diffusible calcium in these cases and that this substance is produced in the placenta. Diffusible calcium values must not be interpreted as meaning the total physiologically available calcium for the control of neuromuscular irritability. The authors offer a working hypothesis to explain the mechanism for the production of tetany in all cases and suggest that spasmophilia in the new-born infant associated with an increased diffusible calcium be termed tetany calcipexicus, indicating a binding or making fast of the diffusible calcium ions. This term will serve to differentiate this type of tetany from the tetany of older infants, tetany due to hyperventilation and parathyroparal tetany.

Polycystic Kidney—In a study of 193 cases of polycystic disease of the kidney, Brunsch and Schacht observed that the average age of the patients at the onset of symptoms was 38.8 years. The average duration of life of the patients reported dead was 50 years. There was definite evidence of a hereditary trend. A systolic blood pressure of 145 mm of mercury or more was found in 61 per cent of the cases, the diastolic blood pressure was more than 90 mm in 55 per cent and more than 95 mm in 47 per cent. Peripheral sclerosis was observed in 15.4 per cent. Retinal sclerosis, with other ocular changes, was noted in 51 per cent. Laboratory evidence of renal insufficiency was present in more than 60 per cent of the cases. Surgical complications occurred in approximately 30 per cent, which is a much greater incidence than is usually recorded. There is frequently a lack of parallelism between the retention and excretory tests for renal function, evidence of reduced renal function is usually greater in the latter. Although a developmental defect probably is primary in the etiology of congenital polycystic kidney, many of the clinical and pathologic manifestations have their origin in an altered condition of the vascular system. Renal polycystic disease is easily overlooked, since there are often no symptoms present that would indicate renal involvement. The renal origin of the patient's symptoms is often recognized only in the course of a routine study of the renal function. The condition may be confused with nephritis unless careful abdominal palpation is made. Failure to discover that renal enlargement is bilateral may lead to the erroneous diagnosis of renal neoplasm. Bilateral urographic studies may be necessary to determine involvement of both kidneys when abdominal palpation reveals unilateral enlargement. The most common symptom is a dull pain, usually referred to either renal region. Urinary symptoms of moderate frequency and dysuria are often observed. Gross hematuria occurs in approximately 33 per cent of cases and may simulate that occurring with neoplasm. The first clinical symptoms are frequently those of renal insufficiency,

although a remarkable degree of tolerance is often noted in the presence of advanced renal destruction. Laboratory evidence of marked reduction in renal function should call attention to the possibility of polycystic renal disease. If renal function remains normal, the prognosis is good. Even moderate reduction of renal function may remain stationary from ten or fifteen years. When the reduction is advanced, the prognosis becomes grave, although several years may elapse before death. The hereditary nature of the disease should discourage the having of progeny, and sterilization should be considered.

Method of Repairing Kidney Wounds—Lowsley and Bishop present the preliminary report of an experimental and clinical study of the repair of wounds of the kidney by a new method of closure which consists in tying broad ribbon gut around the injured part just as one would wrap a parcel with ribbon. The results show that an absorbable gut suture material which is flat and broad like a ribbon can be so placed about the kidney as adequately to approximate the cut surfaces of a nephrotomy incision and to control all bleeding completely. Of twelve animals experimentally operated on, nine have lived in good health up to a period of six weeks. Of the three deaths, one is directly attributable to faulty and imperfect closure of the kidney and the other two resulted from factors not referable directly to the type of operative procedure. Recovery has occurred in all five human cases. Of the specimens observed at necropsy after intervals up to twenty-three days, there has been but one example of imperfect healing and that was due to the fact that too large a pad of hemostatic fat had been added. In all instances the sutures have been found in place and intact. These points emphasize not only that the procedure is possible but that it is permanent in its effect and that the result of such a procedure is compatible with life. Examination of the specimens removed at necropsy demonstrate that renal wounds closed after this manner heal in an entirely satisfactory way with a minimum of reaction as far as can be noted on gross examination. There is no gross alteration of size or consistency in the specimen. It has been noted that the suture material, though absorbable in vitro in from four to five days, has been found unabsorbed at the end of periods up to twenty-three days. Since the material is nonchromicized, this fact strongly suggests that the nephrotomy wounds are tightly closed and do not leak. If there had been seepage, the plain gut would certainly have been absorbed in an interval of this length. Further, the durability of the material offers confidence that an adequate, lasting, supporting structure is afforded until such a time as the healing wound has gained its own strength. The use of fat as a hemostatic adjunct has been satisfactory.

Nephropexy—In a nephropexy Mathe makes the usual curvilinear Albarran incision extending from the costovertebral angle toward the anterior superior spine. The kidney is delivered into the incision and liberated from sclerosing fibrosis or fibrolipomatosis. A triangular twenty-day absorbable chromic catgut suture is taken in the anterior and in the posterior surface of the kidney in the region of the upper pole, in the midregion or in the junction of the midregion and the lower pole, depending on the height of fixation desired. The triangular suture is taken in the renal capsule so as to leave two outer bridges on the surface of the kidney and in the most advantageous position where it would counteract forces tending to bring the kidney to a lower level. The direction of the suture is made so that it is at right angles and not parallel to the framework of the cortex. Suspension at a greater height can be obtained by placing the sutures lower down in the kidney. These sutures are more easily passed through the musculature above the twelfth rib. In cases requiring high suspension the upper anterior and posterior sutures are tied above the eleventh rib. A third suture is taken in the posterior surface of the kidney about 2 cm below the upper posterior suture and is anchored to the musculature below the twelfth rib. The upper portion of the ureter is dissected free from the surrounding structures (ureterolysis) as a routine. In cases presenting an unusual amount of pain denervation or renal sympathectomy is also performed. This consists of severing the sympathetic nerve fibers, which are usually found to course along the superior surface of the renal artery and its main branches. Exposure of the renal artery is facilitated by retracting the renal vein

with a small retractor. In cases in which there is a concomitant perinephritis in which the fibrous capsule consists of a thickened, indurated, sclerotic shell, a small longitudinal incision is made in the capsule on the anterior convex surface of the lower pole of the kidney. The capsule is partially stripped and this is sufficient to release the kidney. A soft rubber tissue drain is placed against the posterior surface of the lower pole of the kidney and is brought out through the upper portion of the skin incision. It is gradually withdrawn about 1 cm each day, in such a way that at the end of a week it is entirely removed. The patient is kept in bed in the Trendelenburg position for three weeks, which assures the adhesion of the kidney to the walls of the renal fossa in a high position. The author states that the results obtained from the use of this method have been satisfactory. Routine postoperative pyelographic study demonstrated that the kidney was permanently fixed in a sufficiently high position by which the ureter was freed from kinks and thus good dependent drainage of urine was definitely established. Relief from symptoms by this method has surpassed the use of all other methods formerly employed by the author.

Treatment of Agranulocytic Angina with Calf Spleen—Gray reports a case of agranulocytic angina with a positive Wassermann test to demonstrate further the value of raw fetal calf spleen in the treatment of agranulocytic angina. The author believes that the extent to which syphilis influenced the patient's condition is a matter of speculation. Because of her so called leukopenic diathesis, which seems to have existed long before she contracted syphilis, the author doubts that it had much part in the causation of the agranulocytosis. While it is entirely possible that this patient may have recovered without any specific treatment and also that she may have a recurrence at any time, he feels as others do who have used it, that raw fetal spleen is of definite, specific value in the treatment of agranulocytic angina. The only objections to its use are the frequent difficulty in obtaining a fresh, adequate supply and the distastefulness for it.

Gonococcal Vulvovaginitis Before Puberty—In treating eight children for gonococcal vulvovaginitis, Stalnaker found that gentle digital rectal stripping of the cervix, vagina and urethra by pressing them anteriorly toward the symphysis pubis is the safest and most beneficial method of treatment. He advocates this treatment in children from the age of 2 upward. In younger patients he gives vaginal douches of potassium permanganate in 1:20,000 dilutions. He stresses the point that natural drainage should be encouraged even to the extent of a tissue diarrhea.

Perforated Peptic Ulcers—Scotson investigated the late results following operations performed for perforated peptic ulcers in a series of 181 cases. In less than 20 per cent there were severe symptoms and in more than 40 per cent there were no symptoms of any sort. Of the duodenal ulcers treated by simple suture 54 per cent of patients who had adhered to the dietary restrictions had no symptoms while of those who had not done so only about 30 per cent were symptomless. None of the duodenal ulcer patients treated by suture and short circuit had any severe postoperative symptoms. In gastric ulcers the effect of dietary restrictions did not seem to reduce the onset of recurrent symptoms.

 Partial Rupture of Old Cesarean Scars with Intact Fetal Membranes. J. S. Tait—p. 1054

Endometrial Tumors of Perineum—Malphrant describes a case of endometrioma of the perineum and presents three other cases collected from the literature. The case described occurred in a patient operated on for a deficient perineum, next day she menstruated and two years later a tumor developed in the perineal scar which showed the typical structure of uterine mucosa. The author suggests that this tumor was a true implant and that it had grown from a fragment of menstrual exfoliation.

Caput Succedaneum—Goodall states that a caput succedaneum forms only after rupture of the membranes. Its diameter and circumference are proportionate and sequential to the diameter and circumference of the neck of the uterus. Its depth is an indication of the sum total of the uterine contraction and the duration of time after rupture of the membranes. Its absence after rupture, when pains are severe is indicative of uterine muscular spasm instead of rhythmic normal contraction. Its role in the first stage of labor is purely passive. In the second stage, owing to its eccentric position on the fetal head, the bulk of the fetal head is thrown out of the axis of the pelvis. This abnormal position can be overcome only by strong uterine contractions. In the absence of such contractions incomplete or faulty rotation of the head of the child is the rule. When forceps are applied and the head is drawn to the vulva, the caput lies close to one blade out of the pelvic axis.

Cardiac Contraction and Coronary Flow—Anrep and von Sarrfeld present experiments that lend support to their former observations by showing that 1. Repeated obstructions of the coronary flow of the blood which occur in diastole conspicuously reduce the blood supply through the artery, on the other hand, equal obstructions that occur during systole have almost no effect on the flow of the blood. This result demonstrates that the blood supply to the heart during systole is negligible. 2. Measurements of the blood pressure between the place of clamping and the muscle of the heart show that during systolic clamping there is no change or sometimes even a rise of pressure in the coronary artery, while during diastolic clamping there is a precipitate fall of pressure. This result demonstrates that the muscle of the heart opposes the greatest resistance to the coronary blood supply during systole and the smallest resistance during diastole. 3. These results were obtained in the heart-lung preparation and in the whole animal in artificially perfused coronary arteries and in arteries that remained in connection with the heart.

Elimination of Injected Urea and Creatinine—After the intravenous injection of creatinine or urea into rabbits Kay and Sheehan made comparisons of the amounts of these substances reaching the kidney in the arterial blood and leaving it in the venous blood. During the first minute after the injection the mean plasma renal extraction ratio for creatinine was 31 per cent, and for urea 40 per cent. During the next twenty minutes the ratio for creatinine averaged 19 per cent and for urea 2 per cent or negative. Later than fifty minutes after the injection the mean ratio for creatinine at low plasma concentrations was 38 per cent, and that for urea at low plasma concentrations 15 per cent. With increasing concentration of either substance in the plasma, a diminishing proportion was removed by the kidney from the blood. It appears probable that the absolute amount of these substances that the kidney can remove from the blood passing through it is limited by a maximal value of about 20 mg of creatinine or 15 mg of urea per hundred cubic centimeters of blood. Combined experiments indicate that, when the kidney is removing large amounts of creatinine from the blood it removes little or no urea from the blood. When it is removing moderate amounts of urea from the blood it can however still remove its normal amount of creatinine from the blood. To explain all the results by a pure "filtration" theory it is necessary to postulate the filtration of from a third to a half of the plasma in the glomeruli and the reabsorption of various amounts of urea and creatinine by the tubular epithelium. According to a pure "secretion"

theory, the tubular epithelium must absorb various amounts of the creatinine or urea in the plasma directly from the inter-tubular capillaries, under certain circumstances up to about half. Either theory, or a combination of the two may be correct, as no fundamental impossibility is involved in the foregoing explanations. The author definitely establishes that under certain conditions a secondary return of urea from the renal parenchyma to the blood does occur.

Blood Lactic Acid in Man During Rest—Cook and Hurst made an attempt to trace the source of blood lactic acid in man during bodily rest and present experimental evidence in support of the following conclusions: 1 During bodily rest the muscles supply no lactic acid to the blood. In the case of men in good training, walking at speeds up to $4\frac{1}{2}$ miles an hour for thirty minutes produces no increase in the lactic acid concentration of blood drawn from the femoral vein. 2 Activity of the sympathetic nervous system with consequent secretion of epinephrine is an unlikely source. 3 Comparison of blood samples taken in immediate succession from the jugular bulb and from an artery during rest shows that the blood receives no demonstrable amount of lactic acid from the brain. 4 The existence of a threshold value below which lactic acid is not resynthesized by the muscles is a hypothesis which lacks supporting evidence of a practical nature and which would still leave unexplained the wide variations in lactic acid concentration. 5 Conversion of blood sugar (glycolysis) is the most probable source of the blood lactic acid at rest. The evidence of glycolytic activity, shown by previous workers to take place *in vitro* and in heart-lung preparations is supported by experiments *in vivo*, in which an increase in blood pH by means of alkali ingestion is shown to increase the blood lactic acid concentration. These experiments also suggest that the variations in lactic acid concentration during bodily rest are due to stimulation or depression of glycolytic activity and assist the organism in its endeavor to maintain a constant blood reaction.

Serum Treatment of Hodgkins Disease—As a result of the publication by Utz and Keatinge of a new form of treatment for lymphadenoma, Barrett and Bond treated four cases of this disease. Their technic was as follows: A fresh portion of blood removed from the patient and kept bacteriologically clean, was emulsified in a small quantity of physiologic solution of sodium chloride and injected subcutaneously into the leg of a chicken. After ten days the chicken was bled and serum was prepared subsequent bleedings being done at weekly or fortnightly intervals. The details of the technic as well as the administration and dosage of serum to the patients were those of Utz and Keatinge. The authors state that a study of their four cases reveals no evidence that the treatment with chicken serum was of any avail or that the disease was controlled in any way. In two of the patients the disease was

certainly advanced when treatment was started, but in the others it may be said to have had a fair trial. The injection of a foreign serum into patients is not without danger, and even in these cases it will be seen that, quite apart from the brisk local and general reaction which sometimes occurred as the dose was increased, other complications arose. In one case an extensive thrombosis of the veins of the arm caused the patient much pain and discomfort and in another the attacks of anaphylaxis were sufficiently serious to be an immediate danger to life.

Autochthonous Calculi of Posterior Part of the Urethra C Edwards—p 516

Autochthonous Calculi of Urethra—Edwards submits a case of autochthonous urethral uric acid calculus occurring in a patient with uninfected urine. It is impossible to conceive the manner in which such stones could be formed without direct association with the urinary tract. Although no fistulous communication could be found between the urethra and the cavities, undoubtedly one must have existed. As it is an impossibility that true prostatic calculi have no connection with the urinary tract, they cannot be formed of urates or uric acid. The author's specimens must therefore be excluded from that category. The dimensions of the stones are such that it would be impossible for them to have passed through the stenosed internal urinary meatus. There was no history to suggest migration and the shape of the stones can be accounted for only by the exertion of continuous pressure on both sides during the period of formation. Such a condition is found exclusively in the prostatic urethra. Migration may therefore be excluded. The author suggests that his patient had (possibly congenital) bilateral diverticula of the posterior part of the urethra. Within these, urates were deposited and ultimately became calcified. Continual additions were made from the urinary stream but the conditions of growth prevented the stones from assuming the usual spherical or elongated form. Of recent years the increasing enlargement of the prostate added its quota of pressure. The history of loin pain may be reasonably attributed to the passage of uric acid crystals, which probably accelerated the onset of vesical symptoms. Phosphates and carbonates formed the most superficial layer of the calculi owing to the fact that the patient was taking alkaline diuretics for about four months prior to the author's observation.

 *Continuous Superior Thyroid Murmur Characteristic Sign of Hyperthyroidism C Lian, L Lyon Chen and R Dumery—p 1942

Continuous Superior Thyroid Murmur—Lian and his associates describe a thyroid murmur which they consider characteristic of hyperthyroidism. They designate it as a continuous superior thyroid murmur, because the maximal intensity is found in auscultation not of the body of the thyroid but of the superior thyroid pedicle within the superior pole of the lateral lobe. The stethoscope should be placed at this point, because the murmur, if it is not intense, may not be audible in the body of the thyroid. It is not necessary to exert pressure with the stethoscope but merely to bring it in contact with the skin. The murmur is continuous and is accompanied by a continuous thrill. It is generally soft during diastole and more or less harsh during systole, it may be whining and musical. It may vary in quality and intensity. As it is a manifestation of hypervascularization of the thyroid, it may be accentuated during the menstrual period or as a result of sympathetic stimulation. The continuous murmur is almost a pathognomonic sign of hyperthyroidism, because it can be confused only with the murmur produced by an arteriovenous cervical aneurysm. This confusion would be possible only if such an aneurysm were associated with a simple goiter (which would be a clinical curiosity) and if the murmur of the aneurysm were localized in the superior thyroid pedicle. The authors observed the continuous superior thyroid murmur in only 20 per cent of cases of exophthalmic goiter; it was found only in cases in which the diagnosis was clear and in cases in which the basal metabolic rate (when measured) was above normal. They consider it the most characteristic single clinical sign of hyperthyroidism.

 Pancreatic Ulcer and Diabetes M Espejo G Avellaneda and J M Romero Martinez—p 941

Electrocardiogram in Myxedema—Carrion and de la Puerta report their observations on the electrocardiograms of two brothers aged 6 months and 2 years, respectively having myxedema, and conclude that the changes in the electrocardiograms of infants presenting congenital myxedema are the same as those observed in the electrocardiograms of adults suffering from the same condition. They discard the hypothesis that the abnormalities of the electrocardiogram are due to alterations of the skin, because they found the same abnormalities in the electrocardiograms taken by means of electrodes with needles hypodermically introduced as in those taken by means of bandage electrodes. They believe unjustified the hypothesis of attributing, in general, the electrocardiographic changes of myxedema to sclerotic lesions of the coronary arteries. In their two patients this hypothesis could not be accepted, owing to the youth of the patients. However, the electrocardiographic changes before treatment were evident, as was also the return of the electrocardiogram to normal after thyroid treatment. The authors believe that there are two periods, representing two phases in the evolution of the myxedematous heart. The first period, of a functional nature, is produced by alterations of the metabolism of the cardiac muscle. In this period the cardiac disturbances are favorably modified by the thyroid treatment. The second period represents a more advanced phase of the disease, in which the organic lesions, consisting of a process of sclerosis due to thyroid insufficiency, are already constituted and developed. In this period thyroid medication does not produce any favorable effect on the disease.

Tabes with Normal Cerebrospinal Fluid—Lopez Albo reports four cases of tabes with normal cerebrospinal fluid. He concludes that the primary lesion in tabes is a productive

chronic granuloma of the posterior roots of the radicular nerves, which sometimes is associated with meningeal inflammation and vascular reaction. In pure granulomatous tabes without complications, the lesions of the radicular nerves are not associated with meningo-vascular reactions. The nerve roots degenerate at the point of location of the granuloma. The motor and sensory cranial nerves show fibroblastic production, while the sensorial cranial nerves, especially the olfactory and optic nerves, are the seat of a process of infiltration. In complicated granulomatous tabes the radicular process coexists with the meningeal inflammation. The reaction is attended by the appearance of plasma cells, fibroblasts and lymphocytes. The cranial nerves show at the same time granulomas and infiltrations of their sheaths and there is also infiltration of the vessels. The granuloma has not a determined localization in the motor cranial nerves. In the cranial ganglions the granulomatous process resides exclusively near the central portion of the root without extending to the peripheral portion. The lesions of the fascicles of the posterior roots and of the columns of Goll and of Burdach are secondary to the fibroblastic granulation. The anatomic alterations of the posterior roots and cranial nerves appear a long time before the clinical symptoms, while in the pure form the clinical symptoms appear before the serologic alterations and, in many cases, the alterations do not appear at all during the entire course of the disease. The recurrent crises of radiculalgia, repeated during several years, are an excellent symptom to diagnose pure granulomatous tabes, even in the presence of normal cerebrospinal fluid. It is of great practical interest to know of these forms of granulomatous tabes with normal cerebrospinal fluid. New investigations are necessary to determine whether the nature of the anatomic process is the cause of the lack of parallelism between the clinical symptoms and the results of the serologic tests.

Immunization by Inhalation of Killed Tubercle Bacilli—Westenyk shows that the inhalation of killed young tubercle bacilli is readily accomplished and well tolerated by rabbits. This method of immunization seems promising, because it produces a satisfactory immunity against relatively large infectious doses in animals. The nature of the resistance is not explained as yet but it is probable that the power of resistance is increased by way of a cellular immunity. The prophylaxis with killed young bacilli and the subsequent inhalation of living bacilli was meant to imitate the natural process in human subjects. The author thinks that, with a different technique, it may eventually be practical in human subjects, but he admits that further experiments will be necessary before this is possible.

Demonstration of Tubercle Bacilli in Feces—Chin Iuk Choun and Krug tried to devise a method for demonstrating tubercle bacilli in human feces in pure culture. They observed in preliminary experiments that by shaking the specimens of stool for thirty minutes with distilled water the accompanying bacteria could be considerably reduced. The sediment is then triturated with 50 cc of a 10 per cent solution of sulphuric

acid and again shaken for thirty minutes. The sediment remaining after this procedure is inoculated into culture mediums. The authors employed one fluid and three solid mediums. The fluid one was a serum containing mineral medium. The solid mediums were the egg-congo red medium (Lowenstein), the egg-malachite medium (Hohn) and the egg medium according to Lubenan-Hohn. The authors examined forty-eight specimens of stool from eighteen patients having open pulmonary tuberculosis. Of sixteen patients whose sputum contained bacilli, fifteen had tubercle bacilli in the stools. In the solid culture mediums 60 per cent of the examined stool specimens were positive, and in the serum containing mineral culture medium 68 per cent.

Schopenhauer and Medicine H Vorwahl—p 1801

Intravenous Serotherapy of Scarlet Fever—Joepchen calls attention to the fact that opinions about the serotherapy of scarlet fever are still divided. Some demand serotherapy for all cases, others advise the use of serum only for the severe and toxic cases, and still others assert that in mild cases serotherapy is fraught with danger in that the number of complications is increased by it. Friedemann is one of those who demand serotherapy for all cases of scarlet fever and he reports favorable results particularly with the intravenous injection of serum. In this mode of application the required amounts of serum are only about one tenth those used in intramuscular injections. Adult require 5 cc, while from 2 to 5 cc is sufficient for children. It was observed that the action is more prompt for fever as well as exanthems disappear much more rapidly than in case in intramuscular administration. Moreover, the incidence of serum disease is considerably reduced. These advantages as well as the small number of complications reported by Friedemann induced Joepchen to investigate the various forms of serotherapy on a larger number of patients suffering from scarlet fever. His observations were made on 220 cases. Of these 100 were treated with intravenous injections of serum 20 with normal horse serum, and the other 100 received no serotherapy. He reaches the conclusion that intravenous serotherapy with small doses may be recommended and that it has advantages over the intramuscular method. However, it influences only the initial toxicosis, the exanthem and the fever and does not prevent complications or reduce their severity. For this reason the author employs serotherapy only in the toxic and severe cases, and he emphasizes that the injection should be made as early as possible.

Acetylene Insufflation in Treatment of Meningitis—Jaurneck considers the use of acetylene gas superior to the use of air in the treatment of meningitis because it is more readily soluble in water as well as in blood and cerebrospinal fluid. Moreover, it is impossible to produce a gas embolism with acetylene, a danger that is not entirely absent in air insufflation. Another advantage of acetylene is its bactericidal and narcotic action. The object of the treatment is to discharge the fluid as completely as possible and to loosen or prevent adhesions. First cerebrospinal fluid is withdrawn until the pressure decreases, and then gas is introduced until resistance is felt. Then more fluid is withdrawn and gas is introduced again. This procedure is continued until the flow of the fluid ceases. The largest quantity withdrawn at one puncture was 200 cc. The patient should be in the sitting position during the intervention so that the gas will ascend to the head. The volume of the gas is generally from four to five times as large

as the discharged fluid. This proves the rapid resorption of the gas. The author performed the lumbar puncture usually under local anesthesia. In two patients the lumbar puncture did not yield fluid and suboccipital puncture was done. Except for a lessened pressure, the procedure was otherwise the same as in the case of lumbar puncture. Following acetylene insufflation, the new formation of cerebrospinal fluid is stimulated. For this reason, cervical stasis is induced by bandaging the neck for several hours and by giving an intravenous injection of from 200 to 300 cc of a 0.2 per cent solution of sodium chloride. The author employed this treatment in eight cases, four patients recovered and four died. The treatment always had a visible, even if only a temporary, effect. The fluid became more clear and profuse, the number of cells and the protein reactions decreased, and the general condition improved. In resorting to acetylene insufflation other treatments, particularly the exclusion of the primary focus, should of course not be neglected.

Controlling Therapeutic Results in Pernicious Anemia—Kruger points out that a noticeable increase in the mean diameter of the erythrocytes is one of the typical symptoms of pernicious anemia and that the determination of the mean diameter is easily accomplished by means of the diffraction micrometry of Pijper. With the help of this method the determination requires only about a minute, and in the hands of the experienced examiner its exactness is greater than that of other methods. The margin of error is only about 0.2 micron. This value is of no practical significance, since the mean diameter of the erythrocytes of untreated pernicious anemia is always from twice to ten times this value greater than the normal mean diameter. Erythrocytometry has diagnostic value (1) in the anisomegalocytosis of pernicious anemia (2) in the isomacrocytosis of many hepatic disorders and (3) in the anisomicrocytosis or anisomicrocytosis of secondary anemia but it is most helpful in pernicious anemia in which it is valuable not only for the diagnosis but also during the treatment. In employing this method of erythrocytometry in a number of patients having pernicious anemia, the author found that the improvement of the blood status is accompanied by a noticeable decrease in the diameter of the erythrocytes, so that normal values may be reached. Unchanged persistence of a large diameter indicates a continuation of pathologic blood formation. The simplicity of Pijper's diffraction micrometry makes it particularly suitable for continuous control of the blood status and thus also for the efficacy of the therapy.

Liver Extract in Treatment of Arsphenamine Toxicoses—Fulst and Fellner admit that the pathogenesis of the arsphenamine toxicoses has not been fully explained but show that a number of investigators have advanced evidence that a dysfunction of the liver is the causal factor. These observations led to the use of liver extracts in the treatment of arsphenamine toxicoses, and the favorable results reported induced the authors to try this method. Immediately after the appearance of the first symptoms of arsphenamine toxicosis they began the intramuscular administration of liver extract. Every second day the patient received an injection into the gluteal muscle. The initial dose was 2 cc which gradually was increased to 5 cc. The total number of injections was from twelve to fifteen. The patients tolerated the injections well and the first effects

of the treatment usually were observed after the third or fourth injection. The efficacy became manifest in rapid improvement of the general condition, reduction of the temperature, improved appetite and betterment of the arsphenamine exanthems. Development of the much feared pyoderma was prevented in many cases. The authors admit that the liver therapy is not the cure all of arsphenamine toxicoses, but in combination with the usual internal and external measures it has given good results, so that they resort to it in all cases of intolerance to arsphenamine. They remark that in the course of injection of liver extracts they dispensed with other parenteral treatments. Immediately after the disappearance of the dermatitis, the arsphenamine treatment could be resumed without further difficulties. The authors resorted to liver treatment also in cases of arsphenamine intolerance without cutaneous manifestations, and again they obtained favorable results.

Mode of Infection in Postoperative Parotitis F. Seifert—p. 729

Results with Freund-Krümmel Intracutaneous Cancer Reaction C. Mirangos—p. 734

Treatment of Malignant Melanoma—Miescher and Schürch present an analysis of results obtained with various methods of treatment of the so-called malignant melanoma. The material consisted of forty-one cases observed in the dermatologic clinic of Bloch and the surgical clinic of Clairmont in Zurich. Twenty-five of the patients were women and sixteen were men. The patients ranged in age from 6 weeks to 83 years. The tumor was located on the face in twenty-five cases, the body in four, the arm in one, the hand in one, the thigh in two, the foot in six, the vulva in one and the mucosa in one. There was one instance of the so-called malignant paraneurium of Hutchinson—a melanoma of the bed of the nail. It ran a characteristic course—involution of the thumb, amputation of the thumb, involvement of the forearm, metastases and death. In twenty-one cases the melanoma developed in a preexisting nevus. History of repeated mechanical or chemical trauma of the nevus was often present. Burning and itching of the nevus were among the earliest symptoms of malignant condition. Biopsy is always contraindicated. The well-known tendency to early metastases and their widespread dissemination find a probable explanation in the existence of thin-walled, easily injured blood vessels as well as in the fact that the malignant cells are held together in a very loose manner. Prognosis depends primarily on the early recognition of the lesion. Localization that subjects the tumor to oft-repeated trauma, such as on the sole of the foot, favors early metastases. The outlook in the presence of metastases is hopeless. Of the thirteen patients presenting themselves for treatment with lymph node metastases, seven were dead a few months after the treatment was begun. Four had a local recurrence and died from metastases. The authors on the other hand do not share the pessimistic opinion entertained with regard to melanoma in general. They point out that in their material as well as in the literature patients presenting themselves for treatment without metastases have not infrequently survived the five and ten year period of cure. Eleven of their twenty-eight patients who had melanoma without metastases were living from one to eleven years after the treatment was begun. The treatment consisted of various methods and combinations of methods such as wide excision of the lesion with the knife, excision followed by irradiation with roentgen rays, irradiation alone, electrocoagulation and amputation of the limb. The authors are not certain as to the best method. They have treated fourteen cases with the method of electrocoagulation and feel that much is to be expected from it. Irradiation alone is not an ideal method in view of the established fact that some melanomas are refractive to roentgen rays. It is to be used only after excision of the tumor. In their experience the act of

operation in itself does not carry the much feared danger of a sudden "explosion" of metastases.

Operative Treatment of Mechanical Ileus—Ravens states that in the matter of operative treatment of mechanical obstruction of the intestine the Kiel clinic is committed to the principle of not opening the intestine for the purpose of emptying it so far as is possible. The opening of the intestine cannot be avoided when existing pathologic conditions demand resection of the intestine or a short circuiting enterostomy or in obturation of the intestine by a malignant tumor. The adherents of enterostomy for the purpose of unloading the intestine after the cause of obstruction or strangulation has been removed argue that distention of the bowel retards the onset of peristalsis and that if permitted to continue the intestine becomes irreversibly paralyzed. To this they add the desirability of ridding the organism of the lethal toxin supposed to exist in the contents of the obstructed loop. On the other hand surgeons opposed to enterostomy argue that the hypothetical lethal toxin has not been definitely demonstrated to exist and that other factors must be taken into account such as (1) irritation of the vasoregulating and visceroregulating central apparatus (reflex theory), (2) profound disturbance of the general circulation with resulting cerebral anemia, (3) dehydration and (4) pathologic contents of the intestine. Performing an enterostomy prolongs the time of the operation while even the slightest spilling of intestinal contents definitely raises the mortality rate. Handling the intestine retards the onset of peristalsis. From 1909 to 1932 439 patients with acute intestinal obstruction were operated on at the Kiel clinic. The mortality amounted to 40.3 per cent. Of these 29 per cent were operated on during the first day of obstruction and 31 per cent during the second and third days. The mortality among those operated on during the first day was 21 per cent. In 100 of these the intestine was not opened and the mortality amounted to only 16 per cent. The mortality rose to 43.5 per cent in the group operated on during the second or third day. In this group the intestine was opened in 54 and the mortality amounted to 68.5 per cent. In eighty-six in whom the intestine was not opened the mortality was 27.7 per cent. Grouping all cases into those in which the intestine was for one reason or another opened (A) and in which it was not opened (B), the author finds that group A is represented by 162 cases with a mortality rate of 63 per cent while group B is represented by 277 cases with a mortality rate of 26.7 per cent. The author admits that the comparison of the results in the two groups is not a fair one for the reason that all cases in group A were far less favorable than those in group B. However the fact that in almost half of the cases the intestine was not opened and that the results were relatively good seems to support his argument that better results are obtained by not operating on the obstructed intestine unless compelled to do so by a definite indication.

Dislocations and Fractures of Cervical Vertebrae—Mackh reports forty-eight cases of fractures and dislocations of cervical vertebrae treated at the Marine Hospital of Hamburg between 1921 and 1932. The material is divided into partial and complete fractures. Under partial are grouped fractures of the spinous processes, the articular processes, the transverse processes and the laminae as well as splitting off from the vertebral body. There were twenty partial fractures and twenty-six complete fractures. Under complete fractures were included (1) dislocation-compression fractures of a vertebra and complete fracture-dislocation, (2) isolated compression fracture of a vertebra and (3) dislocation of a vertebra. Fractures were most frequently the result of an indirect force, such as muscular contraction in a fall on the head, while dislocations most often were the result of application of a direct force. Dislocation may be likewise produced by extreme flexion or extreme extension of the neck. The treatment was conservative along the lines advocated by Magnus. The partial fractures were kept in extension for from two to four weeks. Laminectomy was resorted to only when mild injury or permanent compression of the cord resulted in lesions that were still capable of recovery. The author points out that injury to the cord is produced in most instances by the projecting

posterior fragment, in which case laminectomy does not offer an access to the seat of trouble. The mortality in this group was 5 per cent. Mild neurologic disturbances were present in 15.4 per cent. The second, sixth and seventh vertebrae were most frequently involved. It is not safe to assume that the vertebra is intact on the basis of a single negative roentgen examination. So-called self-reduced subluxation not infrequently resulted in a complete transverse crushing of the cord. Clear cut hemileisions of the cord (Brown-Sequard) are more rare than the individual reports in literature would suggest. Distortion and automatic reduction may occur and lead to residual changes in the cord showing insignificant roentgenologic signs. Death resulting from transverse crushing of the cord is due to a rapidly developing ascending paralysis, which in the course of a few hours reaches the center of respiration. The stiffening operation of Henle-Albee is preferable to the extension treatment of from six to eight months duration to prevent a recurrence in bilateral dislocation with extensive tearing of the suspensory ligaments. For the rest, the conservative treatment of extension in Glisson's apparatus for from four to six weeks followed by a protracted course of physical therapy, was adhered to. The most frequent cause in the group of complete fractures was a fall from a height. Fractures were more frequent than dislocations. The fifth was the most frequently involved vertebra. Involvement of the nervous system was present in 66 per cent of these and complete transverse crushing of the cord in one third of the latter. The mortality in the group amounted to 30 per cent. Callus formation was uniformly satisfactory except in cases of fracture of the posterior portion of the atlas, in which a tendency to pseudarthrosis was noted. Posttraumatic spondylitis deformans was not seen. A mortality of 5 per cent in partial fractures and of 30 per cent in complete fracture-dislocations suggests that the prognosis is not nearly as bad as was formerly held. Neurologic symptoms are capable of further improvement as late as one and one-half years after injury.

Spinal Insufflation in Treatment of Epileptic Attacks

—Friedmann and Scheinker report their experiences with spinal insufflation in forty-three cases of epilepsy. They employed the lumbar method, not the direct filling of the cerebral ventricles. About half an hour before the puncture the patient is given an injection of a mixture of anesthetics (pantopon, scopolamine and caffeine). In children, however, other anesthesia is resorted to. As a rule 10 cc of fluid is withdrawn and 5 cc of air is injected. This difference between the withdrawn fluid and the amount of air introduced is retained, in that after the first injection the amount of fluid withdrawn is always replaced by the same quantity of air. Except when the total volume exceeds 50 or 60 cc the difference may be somewhat larger (from 10 to 15 cc). The quantities of fluid that are withdrawn average between 50 and 150 cc and it was found that not less than from 40 to 50 cc of air should be introduced, since smaller amounts do not give the desired results for diagnosis or treatment. The puncture should be performed if possible in the sitting position. The insufflation is followed by roentgenoscopy of the head from various angles. The authors' observations were made on twenty-six patients with genuine epilepsy, five with late epilepsy, ten with symptomatic epilepsy and two with traumatic epilepsy. They state that the results were good in 25 per cent of the cases, and the treatment was partly successful in 28.3 per cent while the other cases were not influenced. Permanent impairments were never observed and temporary discomfort developed only in a small minority of the cases. In the majority of cases of genuine epilepsy that were successfully treated the encephalogram was normal and the same seems to apply to late epilepsy. However the encephalogram of genuine epilepsy may differ at various times in the same patient. Temporary morphologic

changes in the channels and spaces that contain the cerebrospinal fluid cause this phenomenon. The essential requirement for successful treatment is probably an undisturbed circulation of the fluid. Other factors are probably of only secondary importance. Lumbar insufflation is indicated in cases in which other therapeutic methods fail or are not tolerated and when the epileptic attacks increase in frequency. A repetition of the intervention is advisable, when the encephalogram is not satisfactory, in case of a pathologic picture, in genuine and late epilepsy and in all cases in which the favorable results begin to disappear.

Dermographic Manifestations—Hoff defines as dermatography all visible changes in the blood and fluid content of the skin elicited by external mechanical stimuli. On the basis of L. R. Müller's classification, he differentiates between dermatographia alba rubra and elevata, the latter being accompanied by wheal formation. Some investigators seem to believe that dermatography as such has hardly any clinical significance. The author undertook to study this phenomenon when he noted that dermatographia elevata is characteristic of a certain constitutional type, which in turn indicates that connections exist between dermatography and the organism as a whole. He also observed that in certain neurologic disturbances considerable deviations are noticeable in the dermatographic reaction, which seem to be dependent on the localization of the disturbance in the central nervous system. His report on the latent dermatographic periods of 200 persons indicates that the values increase with advancing age. In persons with thyrotoxicosis, the latent dermatographic period is prolonged. But since the latent dermatographic period shows considerable differences even in normal persons, the determination is of little value for the clinical estimation of thyroid disturbances. Hemiplegia is characterized by a prolongation of the latent dermatographic period on the affected side. In other unilateral cerebral disturbances the latent dermatographic period is usually prolonged on the side opposite the cerebral focus. In some unilateral spinal disturbances there is a prolongation of the latent dermatographic period on the same side. In multiple sclerosis the dermatography values show considerable fluctuations. The author stresses that in neurologic disorders the latent dermatographic period is helpful in determining on what side the cerebral disease focus is located. The one-sided cerebral processes are indicated also by unilateral cyanosis and edemas, changes in the capillaries and localized trophic disturbances. The author advances evidence that each cerebral hemisphere has nervous centers and tracts for the vasomotor function and sweat secretion of the opposite side and that the dermatographic disturbances in neurologic diseases are the result of impairments of vasomotor centers and tracts.

Determination of Hydrogen Ion Concentration—Von Brehmer says that for years efforts have been made to find a reliable method for the detection of the chemical equilibrium in the blood. The shortcomings of the methods hitherto used, such as the titration and the indicator methods, induced the author to approach the problem from the electrophysical point of view. The reaction of the blood is indicated by its content in free hydrogen ions. A gas cell may be built out of a hydrogen electrode, the blood and an acid of a known degree of dissociation. The electrometric force of this cell permits the computation of the hydrogen and hydroxyl contents of the blood. The higher the hydrogen content of the blood the lesser the rapidity of the hydrogen stream into the blood. The streaming of the hydrogen produces friction and this in turn origi-

nates an electric charge. The tension (potential) of this charge increases with the increase of velocity of the stream, and vice versa. Thus the velocity of the hydrogen stream is measured by the potential (P) between the hydrogen electrode and the blood, that is, the hydrogen potential p_H . In short, the height of the potential is inversely proportional to the quantity of the hydrogen ions in the blood. The acidity of the blood is dependent on the quantity of the hydrogen ions, the basicity on the quantity of the hydroxyl ions. The higher the potential, the lesser the quantity of hydrogen ions and the greater the alkalinity of the blood. The most important part of the apparatus necessary for this method is a special needle capable of storing a quantity of hydrogen 800 times its own volume. The charging of the needle with hydrogen is done by electrolysis. He made tests on normal persons, which revealed that the p_H values of the blood increase with the age of the person and that in young persons there exists an acidosis, while with advancing age there is a change toward alkalinity. He relates the results of his tests on diabetic persons, on patients having gastric ulcer and particularly on cancer patients. As cancer was never detected in persons in whom the p_H value was between 68 and 75, he designates these values as the 'neutral zone.' With few exceptions, all cancer patients had p_H values between 76 and 826. The author hopes that with this new method for the determination of the hydrogen ion concentration it will be possible to detect the predisposition to cancer and its earliest stages and, by control tests after operation or irradiation, the efficacy of the therapy.

Treatment of Hay Fever by Means of Type Specific Propeptones—Urbach states that three years ago he called attention to the possibility of treating, by the oral administration of pollen peptones, patients suffering from pollinosis. He has made further studies on this subject, and his proposal to desensitize hay fever patients by the oral administration of pollen propeptones has been supported by the favorable influence obtained from the ingestion of type specific pollens. Chemical experiments disclosed that in the majority of cases the action is bound to the protein fraction. In further experiments, however, it proved possible to prepare propeptones from the protein of the flowers of plants inducing hay fever. This did away with the expensive production of propeptones from pollen or with the oral intake of pure pollen. In patients with symptoms of asthma, it is best to give pure pollen on the empty stomach. After determining the hypersusceptibility and the most offensive type of pollen by means of the nasal pollen test, a trial is made with rye-bran propeptone. If this proves ineffective, treatment with a propeptone from the flowers of various grasses is tried. The advantages of the oral propeptone method over the formerly employed methods are that the treatment does not have to begin until the actual onset of the attacks of hay fever or perhaps a few days before and it is harmless and painless. In cases of hypersensitivity to odors, the treatment with propeptones fails, of course, but the author points out that nonprotein extracts from flowers may be tried.

Thyrotropic Hormone of Anterior Hypophysis in Pregnancy—Müller points out that the thyrotropic hormone of the hypophysis has been isolated and found to stimulate the thyroid. Attempts to utilize it for therapeutic purposes in conditions in which thyroid medication is generally resorted to revealed that its efficacy cannot be compared with that of thyroxine. On reasoning similar to that which induced Kustner to treat eclampsia with thyroxine, the author decided to employ the thyrotropic hormone instead of thyroxine. His experiments disclosed that the thyrotropic hormone did not produce any noticeable effect in healthy pregnant women or in those whose renal function was impaired. The author finds the cause of this failure in the fact that the efficacy of the thyrotropic hormone is inferior to that of thyroxine and that the pharmacology of the hormone is not fully understood. Thus it is possible that the thyroxine is effective while the thyrotropic hormone fails or it may be that the administered quantities of the thyrotropic hormone were insufficient to produce results by the indirect way through the thyroid. The author thinks that further attempts to employ the thyrotropic hormone in the treatment of disorders of pregnancy are not justified until the aforementioned problems have been completely solved.

Suprarenal Extract in Treatment of Psoriasis—In former reports Grüneberg was able to show that when psoriatic efflorescences tend to disappear, there is an increase in the sulphur content of the skin. Since the suprarenals, particularly their cortex, are the most important organ in the regulation of sulphur metabolism, he decided to determine in what manner psoriatic changes in the skin react to treatment with an extract of the suprarenal cortex. Other investigators, particularly Hauck, had tried medication with epinephrine in drops or in the form of tablets but had obtained no results. The author used an extract of the suprarenal cortex, 1 cc of which corresponded to 50 Gm of fresh substance, but the epinephrine content was not in excess of from 1 to 2 micrograms. The patients were given daily intragluteal injections of from 2 to 3 cc of the extract. In all cases generally a few days after the beginning of the treatment, the psoriatic lesions showed signs of retrogression. Only the cases of psoriasis punctata were more resistant and did not react until from two to three weeks after the injections had been begun. An insufficient supply of the extract necessitated interruptions in the treatment of several patients, but the author nevertheless gained the impression that the extract of the suprarenal cortex is more effective in the treatment of psoriatic exanthems than are the liver extracts that have been used in recent years. In a patient presenting polyarthritides, it was noted that the pains disappeared and that the mobility of the joints improved under the influence of the suprarenal extract. Another observation that the author considers worthy of note is the fact that in five of the twelve patients who were treated with the extract the healing of the psoriatic lesions was accompanied by depigmentation. Although this phenomenon was generally only temporary and although leukoderma psoriaticum is not as rare as is commonly assumed, the increased incidence is nevertheless significant. The author considers it an interesting contribution to the hormonal modification of cutaneous pigmentation, particularly, in view of the pigmentation in Addison's disease.

Hormonic Treatment of Arteriosclerosis (Hypertension)—Fellner observed that the female sex hormone effects a considerable dilatation of the vessels of the abdomen, and this led him to believe that this hormone would perhaps reduce the blood pressure. Since experiments on dogs corroborated this assumption, he attempted to treat arteriosclerosis by the administration of the sex hormone. He found that large doses are necessary. In recent times he has treated thirty-seven cases of arteriosclerosis with the sex hormone. He gave daily injections of 1,000 mouse units, but the injections alone were not always effective and so he applied the hormone also in the form of suppositories, containing 2,000 mouse units each, and of which two or three were administered daily. In order to avoid feminization in men, a part of the female sex hormone was replaced by the male sex hormone. An addition of thymus extract, which also has a blood pressure reducing effect, proved helpful in a number of cases. A reduction in the blood pressure usually became manifest from one to three days after the beginning of the treatment, and the sudden reduction was tolerated well by the patients. The anamnesis of several patients indicates that other medicaments had been of slight or no effect. As a rule, the treatment with the sex hormone was continued for from three to four weeks. A number of patients were examined several weeks or months later and, although the blood pressure was not always as low as in the course of the treatment, it was still considerably lower than before the treatment. In two patients the treatment failed completely and in one the effect was only slight, but these patients had refused the injections and had taken only the suppositories. The observations on the other thirty-four patients indicate that large doses of the sex hormone, perhaps with an addition of thymus extract, effect a considerable reduction in the blood pressure of patients with arteriosclerosis.

Blood Transfusion in Pyemia—Jacobson relates his observations on the efficacy of blood transfusion in sepsis. He describes the clinical history of a patient having streptococcal mastitis and a metastasis in the right pleural cavity. After several blood transfusions, the woman finally recovered. The author doubts whether the patient would have recovered without the transfusions, for after the second transfusion a decided change set in. The woman received in all four transfusions, varying in quantity between 150 and 200 cc. The author mentions the various theories on the action mechanism of blood transfusion in septicemia. He himself ascribes its therapeutic value to the increase it effects in bacteriophages, antibodies and immune bodies, and to the fact that it promotes the strength and the resistance of the patient.

Complement Fixation Reaction for Gonorrhea—Budlovsky and Sagher studied 1,050 serum specimens from 900 patients. As antigen they employed a toxin prepared according to the directions of Wolfenstein and Pieper. Their aim was to determine the specificity of the reaction and its value for the differential diagnosis, the prognosis and the establishment of a definite cure. They found that the reaction has a comparatively high degree of specificity and they think that together with the chemical methods it is a valuable aid in the differential diagnosis which in doubtful cases will often help to secure the diagnosis. However they do not feel justified in basing prognostic conclusions on the intensity of the reaction. The relations between clinical cure and the persistence or the negativity of the reaction have not been completely explained as yet. But the authors think that if an

originally positive reaction becomes negative, cure is probable. On the other hand, the persistence of a positive reaction in the presence of the clinical signs of cure should be an inducement for the frequent control of the patient.

Treatment of Wounds with Potassium and Calcium Salts—Hilzensauer followed the suggestion of Schuck and employed potassium and calcium salts in the treatment of wounds. In observations in a large number of cases he found that a sterile 0.6 per cent solution of potassium chlorate applied to an infected wound twice daily in the form of wet bandages cleans it in a short time and produces light red granulations but does not promote epithelization. As soon as the wound has become clean, the potassium chlorate solution should be replaced by a calcium chlorate solution (from 2 to 5 per cent), for calcium promotes epithelization and cicatrization. The calcium solution must be kept strictly sterile. Good results were obtained in many cases of varicose ulcer, in which the calcium solution proved particularly helpful. The best results were obtained in all superficial dirty wounds that did not respond to other treatments, and in all types of skin defects, burns, necroses, infected excoriations, paronychia and all postoperative suppurations. However, in phlegmons, furuncles, carbuncles, osteomyelitis and abscesses of the sweat glands and of the abdominal wall, the treatment did not prove particularly helpful. The author emphasizes that the method is simple and that the pains are slight and generally disappear within a few days. He recommends the method for use in hospitals as well as by the general practitioner.

*Treatment of Pruritus in Chronic Eczema and In Kraurosis Vulvae B Kriss—p 1490
Role of Heart and Vascular System in Diabetic Coma W Falta—p 1491

"Nervous Stage" of Cystitis—Moro shows that the subjective symptoms of cystitis, such as pollakiuria and a burning sensation, frequently persist after the objective changes have disappeared. The measures employed for the treatment of cystitis are not suitable for these functional or nervous disturbances, and the author warns particularly against the use of strong urinary disinfectants. He recommends diathermy, roborants and, in intelligent patients, an explanation of the nature of the disturbances. The patient should avoid exposure to dampness and cold dietary mistakes such as sharp condiments, large amounts of drinks containing carbon dioxide, particularly new beer, and bloating foods. But the patient should not be annoyed with severe dietary restrictions such as abstinence from meat and limitation of the sodium chloride intake, for this is unnecessary and worries the patients. Two cases are reviewed which illustrate the important part of nervous factors in the pathogenesis of these disturbances and the value of psychotherapy in their treatment. The author emphasizes that the symptoms of cystitis may mask grave disorders such

as urinary tuberculosis, calculi and neoplasms of the bladder or the adjoining organs, hypertrophy of the prostate, and misplacement of the bladder as the result of descent or prolapse of the female genitalia

Behavior of Pleura in Pneumothorax—Fleischner observed that fibrin exudation and the formation of adhesions is much more pronounced in the parietal than in the visceral pleura. He reviews cases of internal perforation of old pleural exudates in which the two pleurae showed an entirely different behavior. He also noted that, whenever in the course of exudative pleurisy or of pleural empyema a puncture is made and air enters the cavity, roentgenoscopy reveals that the parietal pleura is covered with a fibrinous layer of considerable thickness while the visceral pleura shows hardly any changes. Such observations are made best on patients undergoing pneumothorax therapy. The exudate does not necessarily have to be large, on the contrary the fibrin deposits are noticeable in cases of small marginal exudates and even in dry pneumothorax. In children and young persons it is frequently noted that the fibrinous layer becomes narrower as the lung unfolds again, however indurations usually develop in adults. The author cites animal experiments by Sorgo corroborating the severe involvement of the parietal pleura and the almost negligible changes on the visceral pleura. Sorgo as well as Fleischner sees the cause of this varying behavior in the different lymphovascular supply of the two pleurae. The author points out that these observations are important for the therapy. Measures inducing hyperemia counteract the lymphatic stasis and prevent, or at least reduce the formation of fibrinous deposits and of indurations. The respiratory gymnastics recommended by Hofbauer are helpful. In patients who have received this treatment the pleural indurations are usually negligible and the author thinks that the early use of active and positive muscular movements promotes the circulation of the lymph and prevents the exudation of larger amounts of fibrin on the parietal pleura.

Treatment of Pruritus in Eczema of Vulva and Anus—To counteract the severe pruritus in cases of vulval and anal eczema, Kriss resorted to subcutaneous infiltration. After disinfecting the skin with benzine he injects either a 0.5 per cent solution of procaine hydrochloride or a 0.2 per cent solution of tutocain. A strong edematization of the region of the labia majora and minora and of the anus is an absolute requirement in this treatment, and therefore it is necessary to inject considerable amounts of fluid. Depending on the extent of the eczema up to 60 cc may be injected. Observations in fifty cases convinced the author that the injections are usually well tolerated. Collapse or other untoward effects were never observed. In many women a single injection was sufficient to counteract the pruritus; in others the infiltration had to be repeated after several weeks. The author's experiences with this method date back seven years and thus he was able to ascertain the permanence of the results in a number of cases.

Bibliotek for Læger, Copenhagen

*Mechanism of Bacterial Infection J. Ørskov—p. 423

Mechanism of Bacterial Infection—The State Serum Institute studied the mechanism of infection with Breslau, paratyphoid B, ratin, pseudotubercle, and abortion bacilli in mice and tubercle bacilli in guinea-pigs, after administration in various ways, and also abortion bacilli in cattle. Ørskov reports that all investigations on oral infection showed that the infections spread in the same way by the regional lymph tracts of the alimentary canal until the regional glands were reached. Generalization occurred from the regional lymph system by way of the blood to the organs and the peripheral glands, presumably as a rule by the thoracic duct and similar centripetal lymph tracts. A primary direct blood infection was never established. The bacteria quickly disappeared from the intestine, not to return until generalization had set in and the number of bacteria was greatly increased. The upper part of the intestine was then often infected earlier than the lower portion which is believed to indicate that the secondary intestinal invasion was due to infected bile. When the general

infections recede, focal processes in organs and glands often persist if these are localized in the liver, chronic carriers, result. The speed of infection and the extent of the various infections vary greatly. In certain cases the size of the primary infection dose plays a part in the intensity of the infection. Study of the mechanism of infection in actively immunized animals showed all acquired immunity to be relative, manifesting itself by increased ability to hinder generalization of an infection and to shorten the duration of infection.

Hemiplegia and Skin Temperature A. Olsen—p. 1097

Injury of Liver Parenchyma in Long Continued Treatment with Barbitol Preliminary Report J. Ravn—p. 1103

*Relation of Bone Marrow to Agranulocytosis Review of Earlier Investigations Together with Personal Observations on Basis of Three Cases A. S. Ohlsen—p. 1113

Hemiplegia and Skin Temperature—Olsen, like earlier investigators, found that in uncomplicated infantile hemiplegia the skin temperature is lower on the parietic side than on the unaffected side. He says that changes in temperature are independent of the degree of atrophy but appear proportional to the strength of spasticity. The skin temperature on the parietic side seems to show a certain relation to the degree of paresis. In almost all cases the temperature on the parietic side and the well side is below the average temperature for well persons.

Injury of Liver in Treatment with Barbitol—Ravn states that out of fifty psychotic patients given daily doses of from 0.25 to 0.75 Gm of barbitol for from one half to five years the urobilinogen test or the bile acid test, or both were positive in thirty-two, or 64 per cent while out of fifty similar control patients not receiving barbitol treatment one or both tests were positive in only sixteen or 32 per cent.

Relation of Bone Marrow to Agranulocytosis—In the first and third of Ohlsen's cases the cell content was about normal, the more mature and fully mature elements of the myeloblast order were absent. The number of mitoses in the myeloblasts was below normal. The erythropoiesis was histologically unaffected and the number of megakaryocytes was normal. Bacterial emboli were found in some capillaries. The second case however was an example of a septically injured, paralyzed bone marrow. The author says that either the bone marrow was primarily different in these cases of malignant agranulocytosis or the patients died at different stages of the disease.

Kidney Function in Diabetes Insipidus—In their case of diabetes insipidus in which one kidney had been removed because of renal tuberculosis Iversen and his associates found a concentration index of about 10 on free intake of liquids. After injection of solution of pituitary there was (1) an initial effect interpreted as spasms of the blood vessels in the kidney with reduction of filtration and (2) a marked effect on the concentration index interpreted as a specific effect in the tubuli shown by increased reabsorption of water. The phosphorus and calcium elimination corresponded in a certain degree to the filtration. The twenty-four hour filtration for the one kidney was 110.9 liters. Injection of 3 mg of epinephrine in thirty-three minutes had no effect on the filtration and but slight effect on the blood pressure.

DIAGNOSTIC, PROGNOSTIC AND THERAPEUTIC NERVE BLOCKS

HENRY S RUTH M D
PHILADELPHIA

Through many experimental and clinical studies, both in this country and abroad there has evolved a technic for injecting, without open section, the majority of the important components of the nervous system. With this accepted and definite technic available regional anesthesia became increasingly efficient and popular. Another result has been the application of these practices as a valuable adjunct to the practice of medicine and surgery along diagnostic, prognostic and therapeutic lines. Just now, numerous conditions are being made the recipients of these methods the reported results of which are frequently contradictory and confusing. I shall here attempt, by a review of the literature on the subject, together with personal observations covering two years of its use, to estimate its present status. It is not within the scope of this paper to consider personal or reported statistics, the results shall be considered in a general way alone.

TECHNIC

The technic for injection of peripheral nerve trunks has been well standardized as evidenced by the textbooks published on the subject.

I believe that, especially in private practice, with all types of therapeutic blocking it is a good plan to advise the patient that it may be necessary to repeat the procedure, in case of failure to relieve the desired results. He should also be told of the numbness following therapeutic alcohol injections of sensory nerves of the hyperesthesias that may develop, especially after paravertebral thoracic alcohol block, that local soreness is often encountered with alcohol injection which remains for a few days and that the maximum relief is not always experienced in the immediate interval following the injections. These injections should be performed without the aid of general anesthesia for the paresthesias during injection are important for more accurate localization. In a neurotic or sensitive patient a preliminary hypodermic of morphine and a soluble barbiturate are administered three quarters of an hour prior to the injection. To insure accuracy, an attempt should be made to induce paresthesias which of course with a pure sensory nerve are elicited in the area of its distribution. Paresthesias experienced during

thoracic sympathetic block are felt in the heart or epigastrium, and during lumbar sympathetic block in the abdomen.

PATHOLOGIC CHANGES PRODUCED BY ALCOHOL INJECTION

The object in injecting alcohol in varying percentages is to destroy the nerve fibers by bringing about degeneration and absorption of all except the neurolemma¹ following more or less directly the original investigation of Schlosser² in 1903 and his subsequent observations.³ The injection of from 80 to 95 per cent alcohol into a peripheral nerve causes a destruction of the motor as well as the sensory components of the nerve.⁴ The pathologic change found in sensory nerves and their ganglion cells is the same as though the nerve had been cut, a wallerian degeneration,¹⁰ with perhaps the possible exception that the intervening fibrosis caused by the alcohol produces a greater resistance to regeneration. It has been shown in experimental injection in animals that 5 cc of 85 per cent alcohol produces a zone of necrosis about 2 cm in diameter.⁵ Because of this fact, injections with alcohol must be more accurately placed as compared to the injections of procaine hydrochloride, for the resulting necrosis of alcohol does not embrace as great an area as the area infiltrated by the same amount of procaine.

Labat,¹¹ after reviewing the experimental data already performed¹² has shown the discrepancy of these conclusions concerning the effect of alcohol in varying concentrations on motor filaments. Some investigators feel that the injection of 60 per cent alcohol produces only a slight transitory motor weakness, although the axonal degeneration of the afferent fibers is quite extensive. Others¹³ have reported quite satisfactory clinical results employing approximately

Owing to lack of space this article is abbreviated as it appears here. The complete article appears in the author's reprints.

Read before the Section on Miscellaneous Topics, Sessions on Anesthesia at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 14, 1933.

33 $\frac{1}{3}$ per cent alcohol, without obtaining muscular paresis or paralysis. Thus there is a possibility of a clinical basis for the apparent resistance of the motor over the sensory components of a mixed nerve to anesthetic agents.

It has been observed clinically that the immediate anesthetic effects of alcohol, injected intraneurally, are not as pronounced as those which may appear several days later. The foundation for this has been explained by Olmstead and Hodgson,¹⁴ who have produced evidence to show that the effects of alcohol block are due to the progressive narcotization of individual nerve fibers in order of increasing size. Consequently one should learn that a supplemental block should not be instituted until the first has been given time for its maximum effects.

Dorrance¹⁵ particularly points out that the results with alcohol injections of nerve trunks are gratifying if sufficient alcohol is employed to produce the necessary destruction. I believe this to be true, but, on the other hand, an excessive amount will spill over into the surrounding tissues and produce there degenerative processes which are most annoying to the patient. His fact has also captured the interest of McLean,¹⁶ who states that a few drops accurately placed has more effect than several cubic centimeters injected into the surrounding tissues. The operator should elicit both referred pain and a sense of resistance to the plunger of the syringe when injecting a single nerve trunk intraneurally.

DIAGNOSTIC AND PROGNOSTIC BLOCK

It appears that there is an increasing tendency to employ regional anesthetic methods for differential diagnosis and prognosis in medical and surgical conditions. Scholl¹⁷ aptly describes one principle of its application by citing a simple case, a postoperative radical mastoid, with persistent pain just posterior to the scar. By injecting the small occipital nerve, he proved the source of the pain to be neuralgia of this nerve, as the pain promptly ceased.

The pathways of pain from the abdominal viscera are the subject of much observation at the present time, hence more knowledge concerning these tracts are continuously being reported. Especially in Germany has this fact been made use of as an aid in the diagnosis of the obscure case.¹⁸ To be a valuable aid in this instance, pain must be a prominent and consistent feature. When the pain pathway from any certain organ is blocked with procaine and the patient's pain immediately ceases, it is good presumptive evidence that the pathologic basis exists in that organ. (A list of pain pathways is given under the discussion on malignancy.) Thus gallbladder disease may be differentiated from

pneumonia, gastric disease, renal disturbances and appendiceal pathologic changes. The same differential diagnostic possibility is true of the conditions named, each with the other, with the exception of renal and appendiceal pathologic changes, in which the segmental innervation overlaps. Its comparative efficiency is also decreased when the pathologic condition has spread to the surrounding tissues.¹⁹ By this method, it is claimed that subsequent operative procedures may be initiated with a more reasonable assurance of success in these obscure cases. Denk,²⁰ by injecting from 10 to 20 cc of 0.5 per cent procaine hydrochloride into the anterior scalenus muscle, interrupts the conductivity of the descending branch of the phrenic nerve. He thus differentiates acute diseases of the upper part of the abdomen from pathologic changes of the lower lobes of the lung.

With the advent in popularity of upper dorsal and lower lumbar ganglionectomy, because of their efficiency in overcoming arterial spasm in the upper and lower extremities, respectively, there arose a need for a diagnostic measure to differentiate poor circulation due to overactivity of the vasomotor nerves (spasm) from arterial obliteration (occlusion), before operation or destruction by alcohol injection was performed. This was first supplied by Brown's²¹ intravenous protein shock, which causes an elevation of superficial temperature in the extremities affected by impoverished circulation due to vasomotor overactivity. This has been discarded by many because of its disagreeable nature causing nausea and vomiting and general discomfort, because it is qualitative and not quantitative, for the rise in temperature is never as great as that which follows ganglionectomy, and because it gives no information as to the amount of pain relief to be afforded by the subsequent operation. The need for more specific information has been supplied by nerve blocking.

The vasomotor impulses to the upper extremity leave the cord by white rami of the upper thoracic segments and ascend to the first and second thoracic ganglions, from which point they travel through postganglionic gray rami to the nerve supply of the arm. For the lower extremity, these impulses leave the lower thoracic and upper lumbar segments and travel through the lumbar ganglions to the nerve supply of the lower extremity. Thus, these vasomotor impulses may be blocked by injection (a) intradurally (b) at the ganglions, or (c) peripherally. After a complete block the superficial temperature rises or the increased rate of blood flow in the corresponding extremity serves as an index to the part of the peripheral circulation deficiency played by vasomotor overactivity.²²

The changes in temperature of the extremity may be measured by the Sheard²³ electrometric thermometer, the Leeds and Northrop multiple point temperature recorder, or the Tycos dermaterm. Eddy and Taylor²⁴ have evolved the normal temperature for fifty-two points on the body surface, which may be used as a criterion in this type of diagnosis.

Morton and Scott²⁶ have formulated a method for standardizing these observations

To block the vasomotor impulses to the lower extremity intradurally, spinal anesthesia²⁶ must be instituted up to the sixth dorsal segment (tip of xiphoid). Any spinal anesthetic agent will yield the same results.²⁷ This is perhaps the simplest form of procedure, but there is some discussion as to whether or not this is a safe procedure for the upper extremity since anesthesia must reach the first thoracic segment. It yields no information concerning the pain-relieving possibilities of a subsequent ganglionectomy, for all pain pathways will be blocked.

Injections of procaine into the thoracic ganglions for study of the upper extremity and the lumbar ganglions for the leg possibly afford the closest comparison to the effects to be produced by the subsequent ganglionectomy. Its effects are more prolonged than with intradural block (from two to four hours) and it obliterates only that portion of pain being transmitted by the sympathetic tracts. I am of the opinion that this form is the most valuable and that with practice it is not technically difficult. The production of Horner's syndrome for the upper sympathetic block and the disappearance of sweating in both upper and lower sympathetic blocks are proofs of the accuracy of the injection.

The Whites³ state that blocking of the sciatic nerve is simple and yields as much information as the two other methods of block. No evidence of pain relief possibilities are given since the main sensory tracts are obliterated. Scott and Morton²⁸ have employed an ingenious form of diagnostic block that may be used in the ambulant patient. By blocking the posterior tibial nerve and observing the temperature change in the sole of the foot, they came to the conclusion that the results were as quantitatively effective as those accomplished by the other types. For a study of the upper extremity, they block the ulnar nerve at the elbow and the median nerve just above the wrist and observe the resultant thermal change in the anesthetized areas. They tested the accuracy of their injections by the inability of the patient to perceive a sharp instrument placed in contact with the anesthetized areas. Lundy employs a technique of his own for the upper extremities by blocking the ulnar nerve and the bases of the fingers.²⁹

AORTIC ANEURYSM

The terrific pain of the terminal stages of aneurysm of the aortic arch has captured the attention of White,³⁰ who has applied paravertebral injections in a limited series with promising results. In each of his three cases he found only the two upper thoracic segments hyperesthetic and consequently injected these two with good results. Therefore as he points out blocking for aneurysm is comparatively simpler than that executed

for angina pectoris, as only two instead of four or five thoracic nerves are to be injected, and the troublesome hyperesthesias have been absent. I have also almost entirely relieved the pain of aneurysm of the abdominal aorta by a bilateral block of the twelfth thoracic and the first and second lumbar nerves with alcohol.

BRONCHIAL ASTHMA

In cases of true bronchial asthma, the literature in general on the subject of relief through interference of the nervous system is quite disappointing. The reports of sympathectomy, however, in the great majority state that cervical and not thoracic sympathectomy was performed.³¹ In two reviews on the literature of the subject, Kern³² mentioned only cervical sympathectomy being executed, and Phillips and Scott³³ in a more extensive review did mention a very few unilateral stellate ganglionectomies but no bilateral sections. Kern³² showed that vagus section caused diminished bronchial motility, a result condemned by bronchoscopists. Heinbecker³⁴ feels that surgery as a form of therapy in asthma has inevitable limitations placed on it by the heterogeneous physiologic functions of the structures available for attack. Since cervical and unilateral stellate ganglionectomy had proved so unsatisfactory in most instances, I felt that possibly bilateral sympathetic block might prove beneficial. Therefore, I have employed procaine hydrochloride and alcohol injections on the lateral aspects of the seventh cervical and first second third and fourth dorsal vertebrae. The results obtained have not been as gratifying as those claimed by DuBose,³⁵ who reports relief in all cases, some for as long as sixteen months. There have been disappointing results in approximately half these cases yet the results in the remainder have been so startlingly successful that I am of the opinion that it is a method to be thought of in all cases that are intractable to the more conservative and accepted lines of treatment.

SYMPATHETIC INJECTIONS FOR VASOSPASTIC CONDITIONS

The autonomic nervous system is exclusively concerned with the involuntary processes associated with the internal economy of the body.³⁶ It has mainly to do with contraction of the blood vessels and inhibiting action of the sweat glands. Leriche³⁷ was the earliest advocate of periarterial sympathectomy for those conditions which possessed an element of arterial spasm. This mode of attack, however, was found to be comparatively inefficient, for the blood vessels were found to receive segmentary innervation from the main nerve trunks and therefore stripping the arterial coat for a few centimeters deprived the vessel of only a portion of its sympathetic innervation.³⁸ Royle³⁸ first demon-

strated temperature change in the lower extremities following ramisection. This led to a mass of experimental and clinical surgery being performed³⁹ from which much can be learned as a basis for performing injections.

It is thought that, if pain is relieved by the diagnostic injection with procaine, either open operation or injection may produce the same results.⁴⁰ An argument that apparently tends to be an argument speaking for injection is the recent work of Brucke⁴¹ and of Tower and Richter⁴² which shows experimental evidence that sympathetic fibers are able to regenerate after sectioning. A reinjection, of course, is of greater ease and facility than a reoperation. Lee⁴³ also believes that either these fibers regenerate or new pathways are formed.

Injections of the sympathetics have been mentioned as being indicated over operation in elderly patients in the poor operative risk types⁴⁴ and in those who cannot afford hospitalization. It should also be employed for the borderline cases in which operative procedures would not be warranted. There have been no fatalities and no severe complications reported with the injection therapy of the sympathetics.

Raynaud's Disease—There is evidence that this condition is a vasomotor neurosis causing a contraction of the blood vessels of the extremities.⁴⁵ Neither injection into the sympathetics nor ganglionectomy is thought of unless other methods of treatment fail. After injection the extremities become warm, pink and dry and pain is usually relieved.

Thrombo-Angitis Obliterans—The rationale of sympathetic injection in this state is based on the fact that there is an element of spasm in the collateral circulation, which becomes dilated through section of the sympathetics to that extremity.⁴⁶ It should not be done unless other methods of treatment fail, trophic ulcers are present, and the disease is progressive. When performed, it is wise to make the injection bilateral for if the disease is present on one side it will occur sometime in the future on the other side. Diagnostic injections should always be performed to establish the knowledge as to whether or not there is sufficient collateral circulation in the limb to indicate a subsequent alcohol injection. Most workers in the field inject the second, third and fourth lumbar ganglions for the lower

limbs, but Stern⁴⁶ blocks the twelfth thoracic, and the first and second lumbar, and uses 8 cc of 95 per cent alcohol in contradistinction to the usual 5 cc for each unit.

Itthritis—This form of therapy is effective only in the so-called nonspecific rheumatoid arthritis or arthritis deformans when associated with vascular changes of pale, cold, clammy extremities and trophic changes,⁴⁷ and before the occurrence of severe bone involvement.

MALIGNANCY

The average patient with inoperable carcinoma has usually experienced the gamut of surgery, radium or roentgenologic therapy or possibly all three. He presents a typical picture which is a cliche of advanced carcinoma. It is a result of dehydration, secondary anemia and autointoxication, the degree of which all too frequently prevents palliative operations. If the course of a sensory nerve becomes involved by the growth an intractable pain is the result. This pain is persistent without remission and often intense preventing normal eating or sleeping and weight and strength are rapidly lost. Without recourse to some manner of nerve sectioning or nerve blocking the patient's medical counsel has no other resort than to the use of morphine in progressively increasing and progressively ineffectual dosages.

General Remarks on Technique—The painful area and its ramifications are carefully studied and mapped out on the skin surface.

If the nerve supply to the growth is entirely sensory, a minimum amount of procaine of 1 or 2 per cent is injected to ease the subsequent injection of from 80 to 95 per cent alcohol. If the nerve supply is both motor and sensory in character, the percentage of alcohol must be diminished by dilution with procaine. I have demonstrated satisfactory results with the use of alcohol diluted to 30 per cent with procaine on these mixed nerves without inducing paresis or paralysis.

Carcinoma of the Face and Neck—Lesions in this location fall under three headings for block purposes:

- A. When the second or third or both of these divisions of the trigeminus are involved.
- B. When the cervical plexus is involved.
- C. When both the trigeminus and the cervical plexus carry pain impulses.

For blocking the branches of the fifth cranial 1 cc of 2 per cent procaine followed by from 1 to 2 cc of alcohol is used. For the cervical plexus 2 cc of 2 per cent procaine and 4 cc of alcohol has been injected for each of the second, third and fourth cervical nerves.

Fay⁴⁸ and Grant⁴⁹ on the other hand both prefer the operative procedures of intracranial neurectomies or posterior rhizotomy following cervical laminectomy. The patients that I have seen however were certainly in no physical condition for such surgical intentions. This seemed to be borne out by one report by Grant in which with operative procedures 20 per cent of the patients died with operative complications. Woodbridge⁵⁰ says it would be logical to reserve operations in case nerve blocking failed. I believe this to be true.

of any locality in the body, for, while many patients are difficult and present a complex problem, many others are relieved very quickly and simply by nerve blocking.

Any deep-set bone pain, pain deeply laid in the sinuses, and deep pain in the ear are the most difficult to solve. Fay⁴⁷ has attempted a complex nerve section operation on the vagus in order to eliminate the distress deep within the ear but encountered only partial success by so doing.

Thoracic Carcinoma—Hembecke⁴⁸ states that too little is known of innervation of the lung to treat pulmonary carcinoma. I have found however, that blocking the upper five thoracic nerves is of material benefit, but occasionally it is necessary to block the lower thoracic nerves as well. All the fibers from the thorax are supposed to leave through the first to the fifth thoracic nerves, but the outer third of the diaphragmatic pleura is supplied by the lower six intercostals,⁴⁹ which must be considered when relief is not obtained by blocking the upper thoracic nerves. It has been stated that section operations in this locality have high mortalities with nerve block, there are no serious complications and no operative mortality. The relief is usually constant because the point of attack the ram communicantes is probably the final common pathway regardless of the route to this point. White⁵⁰ and Abbott⁵¹ both state that the pain from carcinoma of the lungs and pleura yielded to injections of the first second third and fourth thoracic roots 2 cc of 2 per cent procaine hydrochloride and 5 cc of 95 per cent alcohol being used in each. Even though the resulting anesthesia will last for months there is no objection to repeating a paravertebral alcohol block. This has been done as often as six times.⁵² Careful attention to small details of technic must be exercised in this region to obviate puncturing the dura at the intervertebral foramen, with injury to the cord, such as was reported by Molitsch and Wilson with a Brown-Sequard paralysis resulting.

Carcinosis of Abdominal Viscera—For painful malignant conditions in this region Grant⁵³ particularly extols the advocacy of chordotomy. The theory as set forth by him entails logic, yet the results as tabulated seem discouraging because of the occurrence of complications, fatalities and the rather frequent imperfect results considering the risks involved by the operation. This is true even though only a certain unannounced proportion of his series was composed of conditions of the precarious operative risk of advanced malignancy the remainder being osteo-arthritis, painful stumps, tabetic crises and the like.

For blocking purposes the pathways are demarcated as accurately as possible. The viscerosensory reflex may be employed which reflex means the projection of the pain to the surface. According to McKenzie this is explained by the autonomic fiber transmitting its

impulse to the connecting neuron by a synapse in the cord, which transmits it to the higher centers by way of the spinothalamic tract. This connecting neuron has synaptic contact with the cutaneous sensory nerves as well. The higher centers, being accustomed to receiving through this neuron sensory impulses arising in the skin, interpret as rising in the skin all impulses that arrive over the same neuron, i. e., they project the impulse not from the organ from which it was received but to the skin area supplied by these cutaneous sensory nerves. Wright⁵⁴ explains this more simply by stating that when a pain impulse from a viscus enters a certain posterior nerve root, the pain is referred to the skin area supplied by that particular posterior nerve root. Paravertebral block is supposed to produce a section of the ram communicantes through which the autonomic fiber runs.

As a further check on the pain pathways knowledge of the position of the lesion is of material aid. Alvarez⁵⁵ states that impulses from the upper part of the abdomen reach the spinal cord by means of the splanchnics and the white ram communicantes of the sixth to ninth dorsal nerves, and from the inguinal region by means of the genitofemoral and iliohypogastric through the first to the third lumbar. He also states that although the vagus carries a few sensory fibers, these are of no import, which may be explained by citing cases of injury to the upper portion of the cord, which have experienced painless peritonitis. He cites instances in which the anterior roots have also carried sensory fibers, as well as the nerve filaments carried with blood vessels, which tend to complicate the treatment, but he believes that these instances fortunately are rare.

White⁵⁶ has published more intimate information on the nerve supply of the viscera, which is as follows:

Esophagus fifth to sixth dorsal
Stomach seventh to eighth dorsal
Gallbladder right, tenth dorsal
Small intestine, ninth to tenth dorsal
Kidneys twelfth dorsal to first lumbar
Appendix right first to second lumbar

In addition, Wright⁵⁷ also gives the following:

Rectum, second to fourth sacral
Bladder, twelfth dorsal to first lumbar
Prostate tenth to eleventh dorsal
Testis tenth dorsal
Ovary tenth dorsal

From the foregoing it may be seen that a rather definite method of procedure is outlined for the delineation of pain pathways in this locality, the information as to both the situation of the lesion and the viscerosensory reflex being used. With operative procedures exact and definite knowledge as to the entire extent of the pain pathways must be possessed at the time of operation so as to exenterate all these nerves. If this complete knowledge is lacking as is often the case, the patient will experience the risk suffering and inconvenience of a major operation only to have the continuation of some of his pain. Then, too, an operation other than chordotomy has no control over the subsequent extension of the disease. With the nerve block method, additional nerves may be injected if relief from the first injection is not complete, or if later the disease extends beyond the area of the first injections.

Comment—The majority of patients with intractable pain of an inoperable malignant condition experience total or nearly complete relief through alcohol nerve block, carefully and judiciously administered by one experienced in this sort of procedure.⁵⁷ Disappointments do occur, for in the exceptional case no matter what injections are performed satisfactory relief may not be elicited. Nevertheless it is a procedure with sufficient merit to attempt its use in every case of an inoperable malignant condition when the associated pain is sufficiently severe to indicate prescribing opiates.

MISCELLANEOUS CONDITIONS

To complete the subject I should like to add by mere mention alone a variety of conditions in which nerve block has been found to be of value. Harris⁵⁸ particularly, appears to be the most prominent modern advocate for nerve blocking as opposed to open section for major trigeminal neuralgia. The reports of Swetlow⁵⁹ and White⁶⁰ on paravertebral alcohol block to relieve the pains of angina pectoris have probably made this application of the subject the most popular. The employment of alcohol nerve block for the dysphagia of tuberculous laryngitis was numbered among its earliest applications, the course of either the internal laryngeal nerve⁶¹ or the superior laryngeal nerve⁶² being the site of injection. Paravertebral thoracic injections of alcohol have been found advantageous for the treatment of tuberculous pleurisy.⁶³ Labat has written an excellent account of its use for the post-operative pain of thoracoplasties⁶⁴ in which its application appears to be logical. A novel use of alcohol injection has been devised with reported excellent results in a small series of blepharospasm.⁶⁵ Megacolon has been treated efficaciously by injection into the sympathetics.⁶⁶ Sympathectomy for migraine as well as nerve injection⁶⁰ has had little investigation hence its possibilities should be discussed guardedly. A remote application for paravertebral injections has been suggested by

Amorim⁶⁷ for the more rapid and painless healing of fractured ribs and to effect immobilization to a certain extent in patients with pulmonary tuberculosis who cannot withstand thoracoplasties. Injections of various substances always have been prominent in the treatment of sciatica. Weak solutions of antipyrine,⁶⁸ quinine urica hydrochloride⁶⁹ and physiologic solution of sodium chloride⁷⁰ have been used. Both Craig⁷¹ and Stookey⁷² believe together with Labat,⁷³ that it is dangerous to inject the sciatic nerve itself at the sciatic notch because of hemorrhage or damage to the nerve trunk by trauma. Labat and Greene⁷⁴ exploit a novel method of determining the irritable trunks with an electrical percussion hammer and injecting those responsible for the pain with weak solutions (1 part of 95 per cent alcohol and 2 parts of 1 per cent procaine hydrochloride) of alcohol. I have not been able to derive the same degree of success with these injections into the component roots of the sciatic nerve. Epidural injections with weak procaine large quantities of physiologic solution of sodium chloride or a mixture of the two⁷⁵ have received the most credit. Craig⁷⁶ found that the efficacy of one, two three or four injections with an intervening day of from 40 to 60 cc of 1 per cent procaine hydrochloride had the highest percentage of results as an individual procedure and its inclusion with other methods of treatment increased the incidence of relief in every group of procedures employed. I have relieved brachial neuritis by injecting 20 per cent alcohol in procaine into the brachial plexus and intercostal neuritis and neuralgia by means of paravertebral alcohol block of the affected nerves. Injections into the first second and third thoracic ganglions should be considered for brachial neuritis. Since the distribution of sweat fibers to the hands and feet are the same as the vasomotors cervicothoracic ganglionectomy has relieved hyperhidrosis.⁷⁴ Tabetic gastric crises have been relieved by paravertebral block.⁷⁷ Flothow⁷⁸ advocates sympathetic injections for arteriosclerotic pains and trophic ulcers. He also states that they are advantageous in increasing the blood supply before amputation thereby lessening the incidence of nonhealing and painful stumps.

SUMMARY

1 Recent observations have yielded much information on the subject of pain pathways and the therapeutic effect of section of the sympathetics.

2 Major relief from pain and an additional method of therapy has been added by nerve section.

3 Injection of procaine and alcohol into nerve tissue affords an alternative and at the same time a more or less efficacious method of disrupting nerve impulses with possibly a greater field of application.

ABSTRACT OF DISCUSSION

DR PAUL G FLOTHOW, Seattle The neurosurgeon should either do the work or be present when it is done. Often I have found that the results of injection are psychic, and it is necessary for the operator to evaluate the patient in order to come to a proper conclusion as to what measure is to be instituted. Dr Lundy's technic is safer than that of Dr Ruth not only in the dorsal region but also in the lumbar region. I started doing these injections some three years ago and have gained a great deal of experience. My conclusions are as follows: Alcohol injection of the sympathetic nerves should never be employed in any case in which a permanent result is necessary unless there is some contraindication to surgery. The disadvantages of alcohol injection are first that neuritis results, second the injection is not permanent third the injection is a blind procedure and is uncertain. After several hundred injections I have decided that alcohol injection should never be done in the dorsal region except in cases in which surgery is absolutely contraindicated. In this classification I put angina pectoris and some of the malignant conditions. I feel that injection of alcohol can be more freely used in the lumbar region because the neuritis is not as severe and not as constant as it is in the dorsal region. The sympathetic nerves are separated from the somatic nerves by thick musculature making it easier to get a pure sympathetic injection. It is impossible to inject the dorsal sympathetics without bathing the intercostal nerves in alcohol resulting in most cases in a severe neuritis lasting from a few weeks to many months. I wish to emphasize two conditions that are most satisfactorily treated by alcohol injections. My results in angina pectoris have been brilliant. I have had no deaths as a result of injections. Occasionally I find it necessary to inject the right side also. I have had no failures. In this condition the patient is happy to accept the neuritis in lieu of the anginal pain. The other condition I wish to emphasize is arteriosclerotic pain. It is surprising what a great percentage of cases of these old persons suffering with cold, painful feet and intermittent claudication can be relieved by alcohol injection of the lumbar sympathetics. I also use this injection as a preamputative measure and at times amputation has not been necessary as a result of the injection. I do not feel that injection can possibly replace surgery in vascular conditions such as Raynaud's and Buerger's disease, in which permanent maximum vasodilatation is essential. I have tested on the same individual by operating one side and injecting the other. For a few months injection compares favorably with operation, but it does not stand up.

DR GEZA DE TAKATS Chicago I would like to confirm what Dr Flothow said about the alcoholic neuritis particularly in the dorsal region. That is a very serious complication. I remember three patients in whom I made first diagnostic and then therapeutic injections with 30 per cent alcohol for Raynaud's disease. I would never do that again. In the same patients I have had to do sympathectomies. On the other hand in an inoperable carcinoma naturally the alcoholic neuritis is a minor complication. There is one field here which Dr Ruth did not mention although he possibly had some experience with it namely the relief one can offer in inoperable carcinomas of the uterus and cervix. In these patients I have made transsacral alcoholic injections of 30 per cent alcohol into the first second third and fourth foramina and added bilateral alcohol injections at the level of the third lumbar vertebra. This injection of alcohol and procaine hydrochloride will also infiltrate the second and fourth ganglia so that one injection on each side is satisfactory. At the Cook County Hospital in Chicago I had occasion to do many of these and was able to give relief for three or four months. That is about as long as the patients lived. I would strongly recommend this combined method of alcohol injection in the transsacral foramina and an added injection at the third lumbar level to the hypogastric plexus. It is a very valuable method in relieving intractable pain.

DR HENRY S RUTH Philadelphia This has been a rather difficult subject to present within the allotted time in that it has a diversified application as well as because of its controversial character. Some of its applications had to be omitted

and others should have been presented in greater detail. With regard to surgery versus injection, the latter has one aspect of superiority over surgery. Both, of course, when applied to sensory nerves produce numbness in the area of distribution, which at times is quite annoying to the patient. When produced by open section, this numbness is permanent with injection, it is only semipermanent although frequently the pain does not recur concomitantly with the return of sensation. I believe that today the two outstanding applications for this method of treatment are, first, for angina pectoris, and, second, for the intractable pain of inoperable malignant growths.

SUBARACHNOID INJECTIONS OF PROCAINE HYDROCHLORIDE

THE QUANTITATIVE EFFECTS OF CLINICAL DOSES ON SENSORY, SYMPATHETIC AND MOTOR NERVES

JOHN L EMMETT, MD

Fellow in Surgery, the Mayo Foundation
ROCHESTER, MINN

The literature contains very little accurate information about the physiologic events that occur in spinal anesthesia. Many statements are made concerning the action of spinal anesthesia on the various components of the central and peripheral nervous systems, but there is surprisingly little substantial work as a basis.

In recent years, great progress has been made in the diagnosis and treatment of vascular diseases, because of a finer appreciation of the two major types of vascular disease, namely, vascular occlusion and vasospasm. In an effort to distinguish them, methods have been devised to overcome all vasoconstriction, thereby allowing quantitative estimates of the amounts of vasospasm and of vascular occlusion involved. Fever produced by intravenous injection of typhoid vaccine has been successfully used by Adson and by Brown¹ for several years. More recently Morton and Scott² have advocated spinal anesthesia for the same purpose when the lower extremities are under investigation. Local nerve block has also been shown to produce maximal vasodilatation in the region supplied by the nerves that are affected by the injection, while general anesthesia has been demonstrated to produce maximal vasodilatation, as does fever.³ Spinal anesthesia lends itself more readily to determine the amount of the vasoconstrictor element in vascular diseases of the lower extremities than either general anesthesia or local nerve block. Because of this entry of spinal anesthesia into the field of diagnosis, it becomes more apparent that the physiologic action of subarachnoid injection of procaine should be more fully and accurately understood.

Up to the present time it has been felt that the end point of anesthesia is necessary before complete vasodilatation is obtained.⁴ In this paper an attempt will

Work done under the direction of Dr J S Lundy, Section on Anesthesia and Dr G E Brown, Division of Medicine, the Mayo Clinic.

be made to present graphically the sequence of physiologic events that occur in spinal anesthesia with a wide range of dosage and concentration. The study demonstrates the variable factors that determine the action of the anesthetic drug in individual cases and shows that small doses of procaine, not sufficient to produce anesthesia seem adequate to establish complete vasodilatation.

Chart 1—Observations in case 1

MATERIAL AND METHOD

This study was made with the help of Drs. G. E. Brown and J. S. Lundy. The observations were made on unselected surgical patients taken at random and operated on under spinal anesthesia. Patients of a wide range of ages and subjected to various types of operation were included in this series. Patients of one group (cases 2, 3, 4, 8, 9 and 10 in the table) to each of whom a dose of less than 100 mg of procaine was given, were undergoing transurethral prostatectomy or some other cystoscopic procedure. Because of the fact that the temperature of the cystoscopic room was from 27 to 30°C, a control group of patients (cases 5, 6 and 7) were given low doses in a cooler room. One of the latter patients (case 7) was given spinal anesthesia twice two days apart to bring about lowering of blood pressure.

The observations are recorded separately in the table. As can be seen from examining the table the results in the group composed of cases 2, 3, 4, 8, 9 and 10 and in the group composed of cases 5, 6 and 7 averaged nearly the same. For this reason we do not feel that the room temperature, within reasonable limits, has as great an effect on cutaneous temperature for the hour or so during which the patient is observed as has been thought.

A total of thirty-four cases and thirty-five observations are included in the study. Two of the patients were given general anesthesia by inhalation, thirty-one were given spinal anesthesia with procaine, and one was given spinal anesthesia with pantocain. Cases in which there was definite evidence of vascular disturbance are noted in the table in the column headed "complicating pathologic condition." As can be seen many of the patients were of advanced age, among whom arteriosclerosis of some degree is almost always the rule.

The technic used in the induction of spinal anesthesia has been fully described by Lovell. Ampules especially prepared containing crystals of procaine hydrochloride dissolved in physiologic solution of sodium chloride were used. The ampules contained 100 mg of procaine for each cubic centimeter. The solution was taken up into the syringe and the dose estimated from the graduations on the syringe. The additional fluid, to make the desired concentration, was obtained by aspirating spinal fluid into the syringe and then injecting the entire content at the rate of 0.5 cc each second. The bevel of the needle was always toward the head of the patient. The site of the injection was one of the lumbar interspaces.

Three phases of the nervous response were studied and charted according to the arbitrary standards now to be explained.

To determine the sensory response, the patients' lower extremities below the ankles were tested with the point of a pin, and the degree of anesthesia was recorded in four grades as follows: Grade 4 anesthesia—the patient could not tell that he was being touched; Grade 3 analgesia—the patient could feel that he was being touched but a sensation of pain was not produced; He could not distinguish sharp from dull; Grades 2 and 1—the patient could feel that the point of the pin was sharp but could distinguish that it was not quite as painful as it would have been under normal conditions (perception graded 2 was less than that graded 1). Zero—no loss of sensory perception.

To determine the motor response the patient was asked to move the toes, feet and legs, and the degree of motor impairment was recorded in four grades as follows: Grade 4—complete loss of motor function, the patient could not even wiggle the toes; Grade 3, the patient could move the toes slightly and the feet very little; Grade 2, the patient could move the toes and feet freely and could move the legs some but he could raise the legs only slightly and with great difficulty; Grade 1, the patient had good motion in the feet and

Chart 2—Observations in case 5

only moderate weakness of the legs. Zero, no demonstrable motor involvement.

The sympathetic response was determined indirectly. The consensus at the present time is that the caliber of the arteries is controlled by nerve fibers belonging to the sympathetic system and called vasoconstrictor fibers. Stimulation of these fibers produces narrowing of the vascular lumen while block or severance allows

vasodilatation. These fibers pass by way of the white and gray rami and are distributed by the peripheral nerves to the vessels, thereby giving a more or less segmental distribution.⁶

The early work of Brown⁷ on vascular disease produced the method of fever induced by protein shock to increase the blood supply to the tissues. The rise in surface temperature was interpreted as manifesting

cases with those of other authors observed by means of the same and of different methods that one can come to a conclusion that any given case has attained complete vasodilatation. With this explanation in mind the sympathetic system was studied by means of observing the rise in surface temperature of the lower extremities recorded with a portable machine for determination of cutaneous temperature (dermatherm, Tyco¹⁰).

The temperature of the plantar surface of each great toe was taken in most instances. In a few cases, because of lack of space in the cystoscopic room and because the patient was in the lithotomy position it was impracticable to bare more than one foot for determinations. However, even when both feet were accessible there were only minor differences between the temperatures of the two. In all experiments the patients were in the preparation room from fifteen to thirty minutes before the initial readings were taken, to allow for any adjustment to temperature. The sterile linen on the operating table

Chart 3—Observations in case 6

vasodilatation, resulting from vasomotor release. Morton and Scott⁸ later, studying spinal anesthesia, local nerve block and general anesthesia, noted the same rise in cutaneous temperature of the part with the augmented blood supply. They also explained the mechanism as a blocking of the sympathetic vasoconstrictor fibers. These temperatures were spoken of as "maximal temperatures" produced by "complete vasodilatation." There may be other factors that enter into this picture, such as the increased rate of blood flow with fever or the fall in blood pressure so common in spinal anesthesia. However, at the present time it seems that the logical explanation is the one in current use, namely, that these various methods of vascular diagnosis all seek to inhibit the impulses passing by way of the vasoconstrictor fibers. Postoperative results from interruption of the sympathetic nerves seem to bear proof of this theory.⁹ Morton and Scott have conducted a series of experiments on young normal persons trying to establish a minimal cutaneous temperature for the lower extremities which must be reached, if the patient's vascular tree is normal when "complete vasomotor release" or "complete vasodilatation" is produced.

From the foregoing discussion it is seen that when the terms maximal temperature and complete vasodilatation are used in this paper they are so used advisedly. This was a clinical and not an experimental study and it is only by comparison of this group of

was draped loosely over the patient's feet, allowing free circulation of air.

It was the object of the experiment to make frequent observations on the sensory, motor and sympathetic systems. Readings were attempted every two minutes after subarachnoid injection of procaine, for the first fifteen to twenty minutes and every five minutes thereafter until the operation was finished. However, because of the work involved in placing the patient on

Chart 4—Observations in case 7

the operating table and subsequent maneuvers attendant on preparation for operation, this routine was not always possible. Therefore variable periods of time elapsed between readings. In a few cases (cases 5, 6, 7, 16, 18 and 27, charts 2, 3, 4, 5 and 7) the patient was followed from the operating room to his own room and readings were taken until the patient was

free from any sensory involvement and could readily appreciate the prick of a pin. All observations and readings were taken by the same observer. This avoided inaccuracies which would arise from many observers participating especially in interpretation of the arbitrary values used to denote partial sensory and motor block.

RESULTS OF EXPERIMENTS

Results in the thirty-four cases are summarized in the table. They are arranged in order of dosage beginning with the lowest dose given. The graphs shown (charts 1 to 7 inclusive) are representative and have been selected to demonstrate the effects of the anesthetic on the sensory motor and sympathetic nerves of both lower extremities.

The Physiology of Spinal Anesthesia—The usual sequence of events in a spinal anesthetic (cases 5, 6, 7, 16 and 27, charts 2, 3, 4, 5 and 7) is as follows in order of their appearance: 1. Sensory nerve block

Chart 5—Observations in case 16

with analgesia or anesthesia, depending on the amount of anesthetic given. 2. Sympathetic nerve block determined by the rise of surface temperature of the lower extremities, apparently indicating release of the vasoconstrictor fibers. Among older people and those with arteriosclerosis and other conditions in which arteries are occluded this rise usually lags. It is probable that the sympathetic block occurs before the sensory block but of necessity is detected later because of the indirect means of determining it. It seems logical to assume that a definite period of time is required for the skin and tissues of the extremity to take up heat from the rush of larger amounts of blood when the vessels become of larger caliber. This might be likened to releasing steam into a radiator. After the valve has been opened and the steam admitted several seconds is required before the temperature rises appreciably. 3. Motor nerve block: this does not occur unless the dose of the anesthetic drug is fairly large.

In the order of recovery of normal function after spinal anesthesia the events are as follows: (1) recovery

of function of motor nerves and (2) recovery of function of sympathetic and sensory nerves. Return to normal of the sympathetic and sensory nerves is almost simultaneous although one may be slightly in advance usually the sympathetic, as determined by readings of cutaneous temperature. The surgeon nearly always can be warned a few minutes in advance that the anesthesia will soon be insufficient for his patient by observing that the temperature in the extremities begins to fall. The temperature of the digits does not fall to the original level at once but usually stays a little higher than the initial reading for a few hours.

The personal equation is very important in spinal anesthesia and one patient will not react exactly the same as another to the same dose. In general it has seemed in this study that aged patients with arteriosclerosis and debilitating disease obtain a more profound effect and retain it for a longer period of time than younger patients who are in good health (compare cases 5 and 6, charts 2 and 3).

Fractional Block and Its Relation to Dose and Concentration—To the reader who is not acquainted with the doses of procaine ordinarily used throughout the country in spinal anesthesia a word on accepted dosage will be useful. One of the common rules heard is that a milligram of procaine should be given for each pound of body weight. This would result in giving a person of average weight about 150 mg. At the Mayo Clinic very conservative doses of procaine are used. The large majority of patients receive from 100 to 150 mg. Occasionally as large a dose as 200 mg is used but rarely one any larger. Babcock¹¹ has stated that a dose of 120 mg in 8 per cent solution

is an average dose for an adult. Many physicians in this country do not hesitate to use much larger doses.

The following questions arise: Is it possible to produce block of one type of nerve independent of the other two types? Can varying degrees of block be produced in each type of nerve by regulation of the dose? This study allows certain conclusions to be drawn relative to the effect on sympathetic sensory and motor nerves.

First sympathetic nerves will be considered. In case 1 (chart 1) a dose of 45 mg of procaine was given for transurethral prostatic resection. Within seventeen minutes maximal (qualified as has been said) vasodilatation had been obtained but no sensory or motor block whatever. A second injection of 80 mg was then given with complete sensory anesthesia but no increase in the temperature of the digits of the lower extremities. This was the only case in which vasodilatation was obtained with practically no sensory

¹¹ Babcock, W. W. A Textbook of Surgery for Students and Physicians. Philadelphia: W. B. Saunders Company, 1928.

involvement To interpret these phenomena is difficult, for no other doses as low as this, or lower, were given for comparison Doses of from 50 to 60 mg (cases 2, 4, 5 and 7, charts 2 and 4) regularly caused sensory analgesia without anesthesia and produced maximal cutaneous temperatures equal to those obtained by large doses This does not correspond with the statements of several authors that anesthesia is the end point necessary to secure complete vasodilatation Whether it would be possible to lower the dose still further and obtain complete or incomplete vasodilatation without any sensory involvement I am not prepared to say, for no opportunity was afforded to subject patients to such low doses However, from these observations it may be assumed that a dose as low as 55 or 60 mg of procaine in 3 cc of fluid (a concentration of about 18 per cent) injected into the lumbar region, will produce sympathetic block with resulting complete vasodilatation of the vessels of the lower extremities This dose usually gives sensory analgesia but may rarely produce anesthesia (cases 3 and 6) Motor block rarely occurs, and if it does occur it is extremely mild Such doses are therefore all that are needed in diagnosis of vascular diseases to determine the amount of vasospasm, caused by overactivity of the sympathetic nerves, or the amount of arterial occlusion, caused by organic disease Because of the mild sensory and motor effect, this low dose is much safer than the doses usually employed in spinal anesthesia

It will be noticed from the table that maximal temperatures as high as 35.5 C are recorded The average for the series is 32.7 ± 0.155 C In eight cases the maximal temperatures were less than 32.7 C Patient 9 whose maximal temperature was 31.9 C was 67 years of age, had marked arteriosclerosis, and the Wassermann test was positive Patient 11, whose maximal temperature was 28.2 C, was 59 years of age and had marked peripheral sclerosis with calcification of the vessels, but without occlusion Patient 24 was 61 years of age and had undergone extensive resection of the bladder for carcinoma She was in poor general condition and went into a state of shock a marked drop in blood pressure developed, and the patient left the operating room in poor condition Patient 13 was 22 years of age and the maximal temperature was 31.7 C, but observations were made for only twenty-two minutes If this patient had been observed for a longer period the temperature might have been higher In the remaining four of the eight cases (cases 12, 18, 19 and 31) the maximal temperatures were 31.6, 31.9, 30.0 and 32.3 C respectively No explanation for these lower temperatures can be given with the exception that all except patient 31 were considerably more than 60 years of age and no doubt their blood vessels had undergone considerable pathologic change although evidence of it was not noted grossly

Morton and Scott postulated a value based on examination of young, normal persons of 31.5 C as the minimal temperature consistent with complete normal vasodilatation from spinal anesthesia with the room temperature at 20 C They gave a correction of 0.3 degree C to be added for each degree of rise in room temperature in excess of 20 C This value would be approximately 32.4 C with room temperature at 23 C

The foregoing as has been said applies to sympathetic nerves The effect on sensory and motor nerves will now be considered It has been seen that analgesia can be produced without anesthesia and that varying

amounts of motor block can be obtained, depending mostly on dose and concentration of the anesthetic drug and, in minor part, on the individual response of the patient Case 16 (chart 5) represents complete motor block (grade 4) produced by 100 mg of procaine in a concentration of 6.6 per cent, this was the highest concentration used in this series of cases In the two cases in which this high concentration was employed, injection was between lumbar vertebrae 3 and 4 and 4 and 5, respectively The result is to be contrasted with that in case 26 (chart 6), in which there was only partial motor block (grade 3) after 150 mg of procaine in a concentration of 3 per cent had been given between lumbar vertebrae 1 and 2 From these examples it may be seen that dosage and concentration of the fluid bathing the nerve roots is of paramount importance in determining the amount of nerve block that will be produced It therefore follows that no stereotyped rule can be given for production of exactly similar effects in all cases, the wise anesthetist will take concentration into consideration as well as dose weight and age of

Chart 6—Observations in case 26

the patient, and site of injection This point has been consistently advocated by Lundy¹²

Fractional Block and Its Relation to the Factor of Time—Sensory block always occurs rapidly, arriving at its maximum usually within about four minutes, or sooner after the injection However, in occasional cases from two to eight minutes is required

As regards sympathetic block, two columns of the table have been devoted to the time required for the digits of the extremities to attain their maximal temperature after injection For practical purposes the 'practical maximum' would give the information desired in vascular diagnosis From this it is seen that for all useful purposes an interval of thirty minutes after injection probably would suffice However, a few older patients have a slight rise later on to the 'absolute maximum' In most cases there is little or no difference in time between the practical and the absolute maximum but in an occasional case (cases 10, 20, 21 and 25) a difference of ten minutes or more is noted

¹² Es ex H E and Lundy, J S Spinal Anesthesia Laboratory and Clinical Observations S Clin North America 12 10:33 10:37 (Aug) 1932

In case 24, sixty minutes was required to reach the maximal rise in temperature, but the difficulties in this case have been pointed out elsewhere, the sudden, early fall in blood pressure reached a systolic value of 85 mm of mercury and epinephrine was required.

The factor of time in motor block is quite variable. The interval that elapsed between injection and maximal motor effect varied from three or four minutes to twenty or twenty-three minutes, depending on the size of the dose and the concentration. The greater the dose and concentration, the more rapid the motor effect. Debilitated, aged patients seemed to be more quickly and profoundly affected.

COMMENT

It has long been known that the various components of a mixed nerve are not equally blocked in conduction anesthesia. Many workers among whom are Pereles and Sachs¹³ Ioteyko and Stefanowska¹⁴ Hufemann¹⁵ Ostlund, Hodges and Dawson¹⁶ Dixon¹⁷ and Regnier and Desgrez¹⁸ have conducted experiments on nerve

and physical principles involved in nerve block. Niwa,²⁰ Pawlisch,²¹ McGuigan, Cohen and Heinckamp, and Schulz²³ have made contributions with experimental studies. Some men have suggested that sensory fibers are situated more peripherally in a mixed nerve trunk and therefore are more easily reached by the anesthetic drug. Kraus and Ingham²⁴ have disproved this by demonstrating that motor fibers are not any more centrally placed than sensory fibers.

The most logical explanation seems to come from the recent work of Gasser and Erlanger.²⁵ They examined the anterior and posterior roots of the ninth peripheral nerve of a frog and found that the motor fibers averaged about 14 microns in diameter, whereas the sensory fibers averaged about 9 microns. In the motor root they found small fibers that were less than 5 microns in diameter which they felt were the sympathetic fibers. By experiment they further showed that, in cocaine block of a mixed nerve, sensory fibers are blocked first, while, with pressure, motor fibers are blocked first. This work may offer an explanation of our results that, the smaller the nerve fiber, the more quickly it becomes infiltrated with the anesthetic solution.

SUMMARY

The series presented here consisted of thirty-four cases, comprising persons of both sexes and a wide variety of age groups. Thirty-one of these patients were subjected to spinal anesthesia with procaine, one to spinal anesthesia with prilocaine and two to general anesthesia by inhalation. Observations were made at short intervals on the amount of block produced in the sympathetic, sensory and motor nerves with a wide range of doses and concentrations.

The physiologic sequence of nerves blocked in spinal anesthesia was found to be in order of appearance: (1) sensory nerves, (2) sympathetic nerves and (3) motor nerves. However, it is likely that the sympathetic nerves are actually the first to be blocked. The means of measuring sympathetic block is necessarily indirect, depending on the rise of surface temperature of the area supplied by the blocked nerves and because of this delay is recorded after sensory block. The order of recovery is (1) motor nerves and (2) sensory and sympathetic nerves at about the same time.

Chart 1. Observations in case 27.

block using a wide variety of anesthetic agents including alcohol, chloroform, ether, cocaine and heat. They all reported that sensory fibers were more easily blocked than motor fibers. Wiedhopf¹⁹ in 1924 extended his studies to include sympathetic block and reported that the "vessel nerves" were blocked first, the sensory nerves second, and the motor nerves third, which agree with results of this study.

The reason for the results obtained is not entirely clear, for as yet observers are not sure of the chemical

Fractional block is possible. Production of block in one system and not in another by variation of dose and concentration, is feasible. Procaine, 60 mg in a concentration of about 1.5 to 2 per cent is adequate to produce a rise in cutaneous temperature to a level assumed at the present time to indicate complete vasodilatation. Complete anesthesia is not necessary to secure this vasodilatation.

Complete sensory effect is usually had in from four to eight minutes. For practical purposes an interval of thirty minutes after injection should be sufficient to produce maximal rise in surface temperature due to

is an indirect one, namely, by the rise in skin temperature, it is difficult to be sure just when complete vasodilatation takes place. Since the skin temperature is normally in a state of flux, the demonstration of a rise and then a plateau with a fairly high level of about 31 C, or certainly above 32 C, as Dr Emmett has shown in his charts is rather conclusive evidence that complete vasodilatation has been secured.

One should consider what effect the fall in blood pressure coincident with spinal anesthesia may have on the skin temperature since the latter is really a measurement of rate of flow of blood in which vasodilatation is only one factor. The fall of blood pressure seems to be greater from spinal anesthesia than from most other methods of vasodilation. In the

block of the sympathetic vasoconstrictor nerves. The time between injection and production of motor block is variable, ranging from three to twenty-three minutes. All these figures vary greatly according to dosage and concentration used.

ABSTRACT OF DISCUSSION

DR NELSON W. BARKER, Rochester, Minn. One question that will immediately arise is whether Dr Emmett has secured complete vasodilatation. Definite vasodilatation has been demonstrated following general anesthesia, application of external heat and diathermy, ingestion of ethyl alcohol and fever induced by the intravenous injection of foreign protein. However, because the method of measurement of vasodilatation in man

present state of knowledge an arbitrary normal skin temperature representing full vasodilatation cannot be established until more is known about the influence of age and nonocclusive rigidity of the arterial system. It would be valuable to have data concerning complete vasodilatation produced in a single person by a variety of methods finally compared with sympathetic ganglionectomy. It is probable that spinal anesthesia is one of the most accurate methods for producing complete vasodilatation. Its chief disadvantage to the present time has been that it is too great a procedure to be used as a single test. However, with increasing improvement in technique and reduction in the amount of the anesthetic agent necessary, I believe it will be of greater use as an accurate diagnostic method to distinguish the vasospastic and vaso-occlusive factors in peripheral arterial disease.

DR FRANK A KELLY, Detroit In regard to the cases under discussion in which there is a vascular disturbance in the extremities similar to thrombo angitis obliterans or Raynaud's disease and the question as to whether there is an actual plugging of the vessels or whether there is some form of vascular spasm, I have been able to determine the pathology to some extent in the following manner. A saline disappearance test was done in each of these cases showing a gradual diminishing circulation toward the foot with a complete loss of circulation in the foot. The temperatures were then taken by the thermocouple apparatus when the same condition of circulation was evident. I then administered in each of these cases a spinal anesthetic and repeated the tests, both the saline disappearance and the temperature. In one case the circulation showed no alteration under spinal anesthesia, and I considered this evidence of a complete block in the circulation. Operation proved that to be true and proved that ganglionectomy or sympathectomy would do no good. In the other case the same test was made under spinal anesthesia. Some improvement took place, as evidenced by both tests. A lumbar ganglionectomy was done and so far the results have been fine.

DR JOHN L FULTT Rochester Minn. As Dr Barker has suggested final proof of complete vasodilatation by the method here advocated will await a study of cases subjected to surgical interruption of the sympathetic nerves after having been studied by means of subarachnoid block with these low doses of procaine hydrochloride. I hope to be able to report a series of such cases in the near future. Dr Brown has a large series of cases studied by his method of induction of fever in which complete vasodilatation has been proved subsequently by lumbar ganglionectomy. Because of the fact that the maximum temperatures in my cases compare so favorably with those of his studies I feel that maximum vasodilatation has most likely been attained in my cases.

THE ROENTGEN DIAGNOSIS OF CARDIAC ANEURYSMS

DAVID STEEL MD
CLEVELAND

Aneurysmal dilatation of the heart is by no means a rare lesion pathologically. The signs are so indefinite that relatively few cases have been recognized clinically. A still smaller number have been recognized roentgenologically because they often do not produce any change in the silhouette. However, the silhouette is pathognomonic when well marked and it would appear that with care a greater percentage could be diagnosed, or at least suspected, when the changes are minimal.

The earliest reports include an aneurysm of the right auricle by the Dane Olaus Borrich in 1676, one of the right ventricle by the Frenchman Pierre Dionis in Paris in 1696 and one of the left ventricle by the Italian Dominic Galeati in 1757. Since these cases many have been reported. Usually the lesion is single but several aneurysms can be present in one patient as for instance, the case reported by Fujimami in 1900 with three—one at the apex, one in the posterior wall below the mitral orifice and one in the septum, and the case reported by Thuman in 1838, in which there were four in the left ventricle.

In 1926 Pletnew¹ reviewed 300 reported cases of cardiac aneurysms and stated that only six had been diagnosed *intra vitam*. In only one of these six (that of Christian and Erik²) was the lesion visualized by

x-rays, but at autopsy the aneurysm was not at the assumed point. Pletnew added the seventh and eighth cases correctly diagnosed and described the lesion pathologically but he did not show roentgenogram. He considered the roentgen examination of help but not of decisive importance.

Kraus,³ in 1919, reported a case of aneurysm of the sinus of Valsalva. This was described roentgenologically and clinically and verified at autopsy. The first case of cardiac aneurysm of the type discussed in this paper, diagnosed by means of roentgenograms, was reported in 1922 by Szary and Albert.⁴ Here the typical manifestations were present, and there is no doubt that the diagnosis was correct, but the final outcome and autopsy results are absent. Lenk reports a similarly characteristic case but again final proof is lacking. There are other such examples, and therefore it seems advisable to report new cases with roentgen studies and pathologic changes, at the same time reviewing the literature and applying it to the present cases.

Cardiac aneurysms have been variously classified. Kraus divided them into three types as follows:

- 1 Those of the right sinus of Valsalva which perforate into the right ventricle including (a) congenital and (b) acquired. The acquired includes ulcerating processes near the sinus developed subsequent to malignant endocarditis.
- 2 Intraventricular aneurysms in the sinus of Valsalva.
- 3 Partial cardiac aneurysms for the most part due to coronary sclerosis.

The cases presented in this paper fall entirely in the last group, and discussion is therefore limited to this group.

PATHOLOGY

The development of cardiac aneurysms is logically explained on the basis of the pathologic changes and a knowledge of the vascular supply of the myocardium. The coronary arteries are not always constant in their mode of origin and branching but in the average case arise from the root of the aorta, one to the right and one to the left passing inferiorly beneath the aortic valves. The right coronary supplies the anterior portion of the interventricular septum, a portion of the anterior wall of the right ventricle and also part of the left ventricle. From this point of view the left coronary artery is more important. It arises in the left sinus of Valsalva, is usually larger than the right and just below its origin divides into the anterior descending ramus (which gives off large branches to the ventricular septum, the left ventricle and smaller branches to the right ventricle) and the circumflex ramus (which gives large branches to the left ventricle and small branches to the left atrium). Anastomoses are common throughout, not only between the right and left coronary arteries in their capillary and precapillary distribution but also between coronary arteries and vessels of adjacent and attached organs and between branches of each coronary. These anastomoses involve the fine peripheral branches in the subendocardial and subpericardial layers. It is clear therefore that in the anatomic sense of Cohnheim there is no end artery in the heart. In spite of this fact however it has been shown by many workers that the cardiac vascular system is not capable of preventing infarctions when

⁵ Lenk, R. Roentgen Diagnosis of Coronary Sclerosis Intra Vitam. *Fortschr. a. d. Geb. d. Roentgenstrahlen* 35: 1265, 1926.

the larger vessels are occluded. Much detailed work has been done experimentally on the effects of coronary occlusion, and it suffices merely to summarize the valid conclusion drawn by several authors after experimental ligation of the coronaries in dogs.

1 Either coronary can be ligated without necessarily causing immediate cardiac standstill.

2 When one coronary is obstructed in the presence of an existing closure of the other, death ensues either immediately or within a few hours.

3 Obstruction of both the left circumflex and the ramus descendens practically always leads to death, the ventricle stopping first.

4 Occlusion of the entire left coronary⁶ leads to stoppage, the ventricle going into fibrillation. The animal may recover from the immediate effects, but when the area of infarction is large, heart failure takes place from one to three months later.

Conditions are somewhat different in the human being because here there is often an associated myocardial lesion or disease of the coronary elsewhere, and hence occlusion of smaller branches might be of far more serious import. Such lesions are not apt to occur in the average young adult, and if obliteration does take place there is a good possibility that the heart muscle might be spared wholly or in part, at least sufficient for active function due to an adequate collateral blood supply. That the collateral blood supply does take place is evidenced by the fact that the infarcted area is sometimes smaller than the area supplied by the occluded vessel. In an older individual infarction is more common. Experimentally the size of the occluded vessel, its site and the duration and rapidity of the obliteration are important factors in determining the outcome. In the human being there are three added factors, namely, (1) the age of the patient, (2) the condition of the cardiac musculature and (3) the presence or absence of coronary disease in vessels other than the one occluded.

Pathologically, cardiac infarcts show no essential variation from similar lesions in other organs. They have roughly a triangular outline with the base toward the endocardium and the apex toward the epicardium.

Early there is hyperemia and coagulation necrosis. If death does not take place, fibrosis, first appearing in the margins extends throughout. The fibrous tissue arises from preexisting connective tissue. Abundant elastic tissue is present. Muscle fibers become hypertrophic but do not regenerate. As healing progresses the wall

of the infarct near the epicardium becomes thinner, the end-result being a white scar. If this scar is strong enough to resist the intraventricular pressure, no bulging beyond the line of the epicardium will take place. Such a lesion is termed a partial cardiac aneurysm. Even though the wall may be weak its strength may be enhanced by (1) thickening of the

epicardium, (2) adhesions joining the pericardial surfaces or (3) thrombus formation within the sac. Hence bulging may be prevented. In the absence of bulging, the lesion cannot be diagnosed roentgenologically because no change in the cardiac silhouette takes place. If the wall either with or without these enhancing factors, is too weak to resist the intraventricular pressure, bulging beyond the line of the epicardium takes place and a chronic cardiac aneurysm is formed. This is the type of lesion which produces roentgenologic signs and is the type to be discussed. In the cases presented, the aneurysms involved the left ventricle and were caused by infarcts. Actual bulging beyond the line of the epicardium was not marked in any case, as seen at the autopsy, but, since pressure conditions after death are so different from those before death, it is quite logical to assume that bulging was more marked during life than was seen at autopsy.

Fig 2 (case 2)—A large localized bulging is seen in the upper portion of the silhouette of the left ventricle proved at autopsy.

REPORT OF CASES

CASE 1—History—C R, a white man, admitted to the Cleveland City Hospital, Jan 30, 1929, had an indefinite history. His general physical examination showed a few rales at both bases, a faint systolic blow with faint heart sounds and a blood pressure of 115 systolic and a questionable diastolic. His course in the hospital was gradually downhill and he died April 25. A teleroentgenogram (fig 1), taken Feb 1 1929, showed no evidence of any localized bulgings. Oblique views and fluoroscopic notes are lacking.

Autopsy—The heart weighed 600 Gm. When the left ventricle was opened there was a large dilated area involving the anterior wall of the ventricle. It extended to the interventricular septum and measured from 6 to 8 cm in diameter. It was lined by a markedly thickened, pearly white endocardium. The myocardium was entirely replaced by firm scar tissue. In addition there was another dilated area just below the mitral valve. This one measured from 3 to 4 cm and showed similar myocardial changes. Throughout their course both coronary vessels showed many areas of intimal thickening, hyalinization and calcification. Calcification was found mainly in the left descending branch starting just beyond its mouth and extending over an area of from 3 to 4 cm. About 3 cm from its mouth the descending branch of the left coronary was almost completely occluded by an organized thrombus which was gray and very firmly attached to the wall. The circumflex branch of the right coronary artery showed a well marked calcified plaque about 4 cm from its mouth. This almost occluded the lumen. In this region there was a small friable and recent thrombus. The myocardium on cut section showed in addition diffuse scar tissue throughout.

This case showed two large cardiac aneurysms at autopsy but no roentgen evidence in a teleroentgenogram taken in the postero-anterior view. One of these aneurysms was quite favorably located in the left ventricle. It was not visualized in this view, probably because of a lack of bulging beyond the line of the epicardium. Aneurysm can be present, therefore, and give no roentgen signs in such an examination.

Fig 1 (case 1)—Teleroentgenogram showing no evidence of an aneurysm, although two large aneurysms were found at autopsy.

CASE 2—History—E. H., a white man, aged 76, was admitted to the Cleveland City Hospital in a confused state. He thought he had been sick for about three weeks. For the preceding three or four days he had passed no urine. A rupture of the bladder was diagnosed, and air was injected into the bladder and later visualized as free abdominal air beneath the dome of the right diaphragm. He died shortly after admission. Fortunately, a film of the diaphragm was taken so that the cardiac shadow was included (fig 2). It shows a well marked and localized bulging of the upper portion of the left ventricle, quite diagnostic of an aneurysm which bulges beyond the line of the epicardium. This corresponded to the condition found at the autopsy.

Autopsy—The bladder was found ruptured. The pericardial cavity was obliterated. Over the upper posterior half of the left ventricle was a globular bulge. On section there was a defect in the wall measuring 5 cm in diameter at this point. Its upper margin was at the mitral ring, its medial border was at the interventricular septum. The lining, endocardial surface was dense and white except at the bottom where there was a partially organized adherent thrombus. The descending and transverse branches of the left coronary were moderately thickened, sclerotic and slightly narrowed. The proximal 6 cm of the right coronary was sclerotic and for a distance of about 2 cm appeared to be completely occluded by an atherosclerotic plaque except for a pin-point-sized lumen.

The radius of the upper portion of the arch of the left ventricle was smaller than that of the lower. This bulging had increased at the time of discharge from the hospital. A view in the first oblique showed the bulging unusually well and proved its anterior position (fig 4). This proves the importance of this view.

The patient was readmitted the following September. Pulmonary edema developed and the night before death a right-sided hemiplegia was seen. An electrocardiogram showed a delayed intraventricular conduction. At this time a roentgenogram showed the previously demonstrated bulging to have markedly increased in prominence (fig 5).

Autopsy—The heart weighed 500 Gm. The pericardium was smooth and not attached. Both ventricles showed marked hypertrophy. The right was 0.7 cm and the left 2 cm in thickness. At the apex of the left ventricle there was a large, adherent thrombus 8 by 6 by 2 cm. Beneath this thrombus the myocardium was only about 0.5 cm in thickness and appeared yellow, soft and friable. The tip of the septal papillary muscle was involved in a hemorrhagic infarct and separation of its chordae tendineae took place during the examination of the heart. The diagnoses of interest are:

- 1 Myocardial infarction old and recent
- 2 Arteriosclerosis
- 3 Tuberculous pericarditis
- 4 Tuberculous mediastinal lymphadenitis

Fig 3 (case 3)—Taken just before first admission, March 18, 1930. Bulging of the upper portion of the silhouette of the left ventricle is very slight and easily overlooked.

Fig 4 (case 3)—First oblique view taken the same date as figure 3. The localized bulging is easily visualized in this view and is seen to be anterior.

Fig 5 (case 3)—Taken six months after figures 3 and 4, showing the enormous increase in the size of the aneurysm.

CASE 3—History—W. B., a Negro laborer, was admitted to the Lakeside Hospital, March 26, 1930, for the removal of a small lump on the right side of the chest. He had noticed a cardiac palpitation associated with shortness of breath before, and on the day of admission he had an attack during which his pulse varied from 160 to 190. It was regular and associated with no other symptoms save mild dyspnea. The blood pressure was 140 systolic and 85 diastolic. About two months later he was readmitted because of dyspnea. Two weeks previously he was awakened about 5 o'clock in the morning, gasping for breath and with severe "distress" centered over the upper half of the sternum and radiating to the neck. He had no marked pain. His heart was racing and he was too short of breath to talk. He presented the clinical manifestations of chronic bronchitis, emphysema and generalized arteriosclerosis. He improved on rest and digitalis and was discharged improved. At this time an electrocardiogram showed sufficient variation in the PR interval to suggest disease of the conducting system.

Figure 3 is the teleoroentgenogram taken just before the patient's first admission. In retrospect this shows a localized bulging of the upper portion of the left ventricular silhouette. It is important to note that at this time the bulging consisted of only a slight increase in the upper portion of the ventricular

This case is important because it shows an early stage of what later turned out to be a large ventricular aneurysm. It is important also to note that in the early stage the bulging is very slight.

CASE 4—C. M., a white physician, aged 50, seen as a private patient of Dr. R. W. Scott, presented himself with a typical story of coronary thrombosis. He had had attacks of pain in the region of the heart and this pain radiated down the left arm. He had been seen off and on for the preceding four years and at times had attacks of severe shortness of breath and pain. He recently died in one of these attacks. An autopsy was not performed. No proof is needed to explain the silhouette seen in figure 6. The aneurysm is unusually well marked. This plate was taken three years before his death.

CASE 5—H. R., a white man, aged 48, was first seen at St. Luke's Hospital of Cleveland following a severe attack of pain in the left shoulder and heart while swinging a sledge. He remained in the hospital for four weeks, gradually regaining his strength. His second attack occurred, Feb. 8, 1931, and he was admitted to the Cleveland City Hospital. At this time his blood pressure was low, 90 systolic, 60 diastolic. There was nothing striking otherwise in his physical examination. He made a fair recovery and was discharged with a diagnosis

of coronary thrombosis. A teleroentgenogram was taken at this time (June 24) (fig 7). The same type of bulging is seen as in the other cases. The patient has since died, an autopsy was not performed.

CASE 6—History—M. C., a Negro housewife, aged 42, who had been admitted twice to the surgical service of Lakeside Hospital, was admitted to the medical service in June, 1931. She had had a hypertension since 1924. She was admitted to the medical service because of dyspnea of three months' duration. She had never had pain, but on several occasions she had vomited. Her physical signs and history led to a diagnosis of severe myocardial damage and an electrocardiogram suggested a myocardial infarct. She was discharged improved, but had two subsequent admissions, and each time she was in a little worse physical condition than before. Hers was considered a case of coronary thrombosis from the start, and in this case the roentgen examination was of considerable interest.

Her first roentgen examination was on April 17, 1931. The teleroentgenogram, reproduced in figure 8, shows a slight bulging of the upper portion of the left ventricle. The diagnosis was made fluoroscopically. This region of the ventricle showed a slight increase in the amplitude of its pulsations, and these pulsations did not follow in orderly sequence with the remaining portions of the ventricle. They were not definitely expansile when the other portions were contractile. It was quite apparent from watching the screen that pulsations were different in the two portions of the same chamber. The examination was repeated two months later, but the pulsations

The aorta was of average diameter but of reduced elasticity. Its intimal surface was thickened in places by raised, yellow, gray plaques which on section were seen to be intimal thickenings. Some longitudinal wrinkles were present, but these disappeared with tension on the aorta.

ROENTGENOLOGIC DIAGNOSIS

It is evident from a summary of these cases that the lesion can be present (as in case 1) and yet give no roentgen signs. When the lesion is well developed, it appears as a sharply defined bulging of the upper portion of the left ventricular silhouette. This bulging might amount to only a very slight increase in the curving of this portion of the ventricle, but it can be so well marked that an incisura is formed between it and the lower or normal portion of the ventricle (figs 5 and 6). In either case the radius for the upper or aneurysmal portion is smaller than the radius for the lower or nonaneurysmal portion.

It is stated in the literature that the pulsations are quite characteristic. When systole starts in the ventricle, the intraventricular pressure is naturally increased. It is this pressure that the aneurysm has been unable to withstand, and it shows this weakness fluoro-

Fig 6 (case 4) — Unusually well marked localized bulging in the upper portion of the left ventricle.

Fig 7 (case 5) — Undoubted case of aneurysm of the left ventricle.

Fig 8 (case 6) — Minimal bulging in the upper portion of the left ventricle.

could not be demonstrated. Examinations were repeated on July 1, 1932 and November 12, and again the pulsations first described could not be made out, nor was there any roentgen evidence of a cardiac aneurysm.

Autopsy—The heart weighed 612 Gm. Both the right and the left side were dilated and the walls relatively increased in thickness, measuring 1 cm and 3 cm. in thickness, respectively. The visceral pericardium was thickened over an area near the apex of the left ventricle measuring approximately 2.5 cm. in diameter. Beneath this area the wall of the ventricle was thinned to 1 cm. and was soft. On section it was seen to be made up of strands of grayish-white, fibrous tissue. The atria were normal in size and showed no gross pathologic changes except hypertrophy of the pectinate muscle. The valvular mechanism was intact. The pulmonic valve showed no gross pathologic changes. The edges of the mitral aortic and tricuspid valves were irregularly thickened by raised, yellow, firm plaques, which on section were seen to be endocardial thickening. The endocardium was smooth and glistening. The papillary muscle and chordae tendineae were larger than usual but rounded throughout. The coronary vessels were normal in distribution but showed narrowing of their lumens, owing to yellow, raised firm plaques beneath their intima. The descending branch of the left coronary was lost in the soft area described.

scopically during systole. When the other portions of the ventricle are in systole, the weakened wall of the aneurysm dilates, and hence during ventricular systole the aneurysm shows expansion. This phenomenon is spoken of as "systolic movements of systolic expansion."⁴ It was this type of pulsation which might have been present in case 6, but the pulsations could not be definitely timed. It will be remembered that in this case unusual pulsations were seen at the first fluoroscopic examination only and that these pulsations could not be made out subsequently. It seems quite probable that these pulsations were present only during the early stage of the infarction and that, as organization took place, the wall of fibrous tissue seen at autopsy was strong enough to withstand the intraventricular pressure and hence destroy the pulsatory phenomenon. It seems possible, therefore, that careful examination of the pulsatory phenomenon early in the course of the disease might give supporting or actual diagnostic evidence. In this case it was the only roentgenologic evidence elicited. It seems more than likely that the changes in pulsations were due to aneurysm with little

if any bulging beyond the line of the epicardium. It might be possible to diagnose infarction when the process is new and favorably situated in the silhouette.

There are a number of other signs that might be of importance but they are all secondary to the two just mentioned. For instance it is quite apparent that the aneurysm must always form a part of the cardiac silhouette no matter how the patient is rotated. The shadow has the density of the cardiac silhouette in general but in the cases reported in the literature the shadow is variously described as denser and lighter than the heart shadow. In the case reported by Bianchi⁷ the coarser features of the lung tissue could be made out through the aneurysmal sac. Homogeneity also varies. For the most part this is even but in the case reported by Savary and Albert the periphery of the aneurysm was denser than the central portions. By the aid of the Bucky diaphragm Lenk was able to make out two parallel lines of calcium within the shadow of the heart and these were interpreted as changes in the coronary arteries. Since similar changes in the aortic ring have recently been demonstrated it is not unlikely that with further refinement of technic streaking due to calcification will become more common. It is also possible that small flakes of calcium will be demonstrated in the walls of the aneurysm but with the present technic these are not visualized. This is not difficult to understand when large pericardial calcifications are often obliterated by motion. Wiberg⁸ describes fixation of the apex which he ascribes to pericardial adhesions. This was not demonstrated in any of the present cases.

SUMMARY

Six new cases of chronic cardiac aneurysms are presented and the silhouettes are shown. The absence of roentgenologic evidence of an aneurysm does not rule out the latter. It is quite evident that a careful fluoroscopic examination in the various degrees of rotation is most essential and it seems probable that with more careful search the cases will be more commonly diagnosed. Judging from case 6 it seems likely that cardiac infarction when large enough and favorably situated can be suspected roentgenologically. Since the autopsy in this case was done so long after the observation of the unusual pulsatory phenomenon, no certain conclusions can be drawn. When the cardiac aneurysm is well developed the roentgenologic method is the only means of positive diagnosis, especially in those cases in which the history is not available.

Lakeside Hospital

ABSTRACT OF DISCUSSION

DR FRED J. HODGES, Ann Arbor, Mich.: Dr. Steels' reference to the roentgenologic recognition of cardiac infarcts is particularly interesting and in view of the increasing importance of coronary occlusion as the cause of sudden death any method of its recognition will bear thorough exploitation. During the past year at Ann Arbor Wilson and his associates have made exhaustive experimental studies of cardiac infarction in dogs producing all manner of coronary occlusions and making detailed electrocardiographic studies followed by detailed post mortem observations. They feel as the result of this work that in the large majority of cases the location, extent and duration of myocardial damage can be determined with considerable accuracy from the electrocardiographic curves.

⁸ Wiberg, Gunnar. A Case of Aneurysm of the Heart. *Acta radiol.* 12: 562, 1931.

Although a number of myocardial infarcts have been recognized clinically and post mortem in the University Hospital roentgen studies have not been of any assistance in localizing or, in fact, even recognizing the infarcts. There is only one recorded case of true cardiac aneurysm in our hospital records for the past three years. In that one case roentgen studies were limited to a single exposure in the anteroposterior projection because of the patient's critical condition. That one exposure was made with bedside apparatus. Had it been possible to make lateral views, the aneurysm would certainly have been clearly visible. For at autopsy it appeared as a rounded mass about 3 cm. in diameter projecting from the posterior wall of the heart. Since cases of cardiac infarction frequently come under observation only when the patient's condition will not permit of exhaustive roentgen study it stands to reason that even readily demonstrable lesions will frequently be missed. Of all cases admitted to the University Hospital since 1923, only three ventricular aneurysms have been demonstrated at autopsy. I cannot share Dr. Steels' enthusiasm to the extent of believing that roentgenology will be of any considerable assistance to the clinician in localizing or even recognizing cardiac infarct. He has outlined however an interesting field of endeavor wherein any scrap of information that can be placed at the clinician's disposal is distinctly worth the effort required.

DR DAVID STEEL, Cleveland: I do not mean to leave the impression that cardiac infarcts can be diagnosed roentgenologically. I meant to leave the impression that at the time of the acute attack when infarction might well have taken place pulsations were seen in the region of the ventricle and a diagnosis of localized destructive process in the myocardium was made. That phenomenon was not seen in my subsequent examination but at autopsy the aneurysm occupied the place where the pulsations were found and I think that the pulsations of the infarct, rather than of the aneurysm itself, were seen.

GANGRENE DUE TO THROMBO-ANGIITIS OBLITERANS

FURTHER EXPERIENCES WITH TREATMENT

SALL S. SAMUELS, M.D.
NEW YORK

In March 1931 I¹ made a preliminary report of a new method of treating gangrene of the extremities in thrombo-angitis obliterans. Since that time I have had the opportunity of treating a larger number of these cases and have followed the progress of some previously reported. In this communication I shall describe additional details that are important in the successful treatment of gangrene.

I must at first reiterate my previous conclusion to the effect that extreme conservatism in thrombo-angitis obliterans is not only desirable but obligatory. The unnecessary mutilation of young men suffering with this disease must be considered a relic of medieval surgery, having no place in the modern treatment of this malady. During the past eight years I have examined and treated more than 300 cases of thrombo-angitis obliterans and in only one instance was it necessary to perform an amputation of the leg. This brings my percentage of amputation in thrombo-angitis obliterans to less than 1 in comparison with percentages of 14 and higher quoted by the sponsors of other methods of treatment. This single amputation occurred in a patient aged 57 in whom the gangrene had spread upward from the plantar surface of the foot to the ankle and heel. This very unusual location of the gangrenous process had destroyed the entire weight-bearing portion of the extremity and had thus removed every possible

From the Manhattan Polyclinic of the City of New York.

chance of healing into a stump of any value to the patient. The unusual severity of this isolated case may be explained by the presence of superimposed arteriosclerosis, which is common in patients over the age of 50. At this point it is important to state that the youth of the majority of patients suffering with this disease is one of the greatest assets in the healing of ulceration and gangrene. The recuperative power of these young individuals is amazing and should not be underestimated.

REPORT OF CASES

Case 1 was described in my previous communication. At that time, however, complete healing had not yet occurred. As the foot is now healed and has remained so for the past two years, I shall describe this case in greater detail.

CASE 1—E M, a man, aged 43, Jewish, born in America, was originally observed by me in 1928, at which time he complained of intermittent claudication and coldness of the right lower extremity. The diagnosis of thrombo-angitis obliterans was made, and the patient was advised to stop smoking and to take intravenous injections of hypertonic sodium chloride solution. The patient, however, did not cooperate. He continued to smoke excessively and neglected treatment entirely. In June 1930, two years later, he reappeared with massive gangrene of the right foot (fig 1). The oscillometric index² at the right ankle was 0. Amputation of the leg was advised at one hospital as the only means of relief. The patient fled in terror and took to his bed at home. At this point I took charge of the case and instituted the course of treatment that I shall describe later. Within a short time a line of demarcation was established and

Fig 1 (case 1)—Massive gangrene of right foot

within five months the gangrenous portion had separated spontaneously (fig 2) leaving a clean, granulating ulcer. After a few weeks the ulcer healed (fig 3) and the patient resumed his work as fireman in a boiler room. At present he can walk without discomfort, has gained weight and requires no orthopedic appliance in the shoe of the amputated foot.

Treatment applied in this case was rest in bed, cessation of smoking, intravenous saline injections and wet dressings of chloramine solution to the foot.

CASE 2—J H, a man aged 40, Jewish, born in Russia, examined by me in October 1930, had two brothers who had been affected with thrombo-angitis obliterans.³ They had died of coronary attacks before the age of 40, most likely caused by lesions of thrombo-angitis obliterans in the coronary arteries.⁴ Up to the time of my treatment the patient had been smoking cigarettes excessively and came to me with deep cyanosis of the left foot and gangrenous ulcers of the second and third toes. The oscillometric index at the left ankle was 0. In spite of intense treatment the gangrenous process spread rapidly so that within six weeks all the toes of the left foot including a

part of the dorsum of the foot, were completely involved (fig 4). A short time later a line of demarcation became evident on the dorsum of the foot, and healthy granulations appeared along the proximal border of the gangrenous area. This was soon followed by sloughing of the dead tissues, including bones and tendons. A clean granulating ulcer remained, which was completely healed six months after the initial treatment (fig 5). The patient is able to walk without

Fig 2 (case 1)—Gangrenous portion after sloughing

the use of any orthopedic appliance. The treatment in this case consisted of rest in bed, cessation of smoking, intravenous saline injections, chloramine foot baths and anesthetic ointments.

CASE 3—M H, a man, aged 38, Jewish, born in America, had had his left leg amputated elsewhere eight years previously for extensive gangrene. Following the operation he continued smoking, and seven years later gangrene of the first two toes of the right foot developed (fig 6). At this stage of the disease I was called to see the patient. The oscillometric index at the right ankle was 0.25. The circulation in the limb had

Fig 3 (case 1)—Appearance of feet after healing of ulcer

apparently been so greatly impaired that all efforts to check the spread of the gangrene were futile. Within two months all the toes were involved and a line of demarcation was finally established in the region of the tarsometatarsal joints. As can be seen in figure 7, the unusually severe case of sloughing of dead tissue including all the metatarsals, tendons and part of the internal cuneiform was eventually followed by the formation of healthy granulations and epithelium. The patient has gained considerable weight and will soon attempt to walk.

⁴ Samuels S S and Feinberg S C. The Heart in Thrombo-angitis Obliterans. *Am Heart J* 6:253 (Dec) 1930.

Treatment in this instance followed the usual routine of rest in bed, cessation of smoking, intravenous saline (5 per cent) injections, chloramine foot baths and anesthetic ointments. At no time during the course of treatment was the patient receiving more than 1 grain (0.06 Gm) of codeine a day. Most of the time, acetylsalicylic acid was sufficient to control the slight pain and discomfort.

CASE 4—H B, a man, aged 47, Jewish, born in Austria, whose history was given in my previous communication as an example of the healing process in thrombo-angiitis obliterans, has now a completely healed ulcer. The patient has been a

Fig 4 (case 2)—Gangrenous involvement

Fig 5 (case 2)—Healing after sloughing of dead tissues

bartender for the past two years. He can walk long distances with no discomfort and has gained considerable weight. He has not resumed smoking. The only deviation from the routine treatment in this case was the patient's insistence on getting out of bed before the ulcer was completely healed. This prolonged the healing time.

CASE 5—M P, a man, aged 40, Jewish, born in Russia, observed in February, 1930, was suffering with a large gangrenous ulcer of the left heel, extending down to the os calcis (fig 8). The usual treatment was instituted with the exception of the strength of the saline solution. Because of the tendency to local thrombosis of the arm veins at the site of injection with 5 per cent sodium chloride, it was necessary to change to 2 per cent solutions. After nine months the ulcer was healed except for a small opening in the center, about 1 cm in diameter, which appeared to lead to the os calcis (fig 9). A roentgenogram of this bone showed no gross changes and no osteomyelitis. In spite of this small opening,

Fig 6 (case 3)—Gangrene of first two toes

the patient can stand and walk without discomfort. His general condition is excellent and he has gained considerable weight. The location of the gangrene in this case is extremely unusual.

CASE 6—B S, a man, aged 33, Jewish, born in America, had had symptoms of thrombo-angiitis obliterans for four years prior to the formation of an ulcer on the left big toe. He had always been a heavy smoker having consumed as many as fifty cigarettes in a day since early boyhood. When seen in April, 1931, he was in extreme pain caused by a foul necrotic ulcer of the left big toe. Previous physicians had performed periarterial sympathectomy on the leg and had prescribed morphine in large quantities, all to no avail. The oscillometric

index at the left ankle was 0.3, which offered hope of a good outcome. The usual treatment was instituted, with strong accent on immediate cessation of smoking. Spontaneous amputation of the necrotic toe soon occurred and after thirteen months the foot was completely healed. At present the patient is working at his usual occupation, has no complaints and has gained considerable weight. Surreptitious smoking probably accounted for the unusual duration of healing time in this case.

CASE 7—H T, a man, aged 28, Jewish, born in Austria, was first seen by me in August, 1931, when there was complete gangrene of the left big toe and a sloughing ulcer about 3 cm in diameter on the dorsum of the left foot. The left foot and leg were markedly edematous as high as the knee. The pain was excruciating, and in order to obtain relief the patient had found it necessary to sit up in a chair day and night continuously for over four months. The dependent position of the extremities accounted for the edema. He had been a heavy smoker since boyhood. The oscillometric index at the left ankle was 0.2. The patient was put to bed at once and the dependent position of the legs was forbidden. After twenty-four hours in the horizontal position the edema of the legs and feet disappeared. The gangrenous member was bathed in chloramine solution and soothing ointments were applied. Every other day 300 cc of 5 per cent sodium chloride solution was given intravenously. Smoking was stopped immediately.

As the big toe healed, the adjacent toe became gangrenous and sloughed off after a few weeks. Eight months later the foot was completely healed and the patient was able to walk at least a mile without discomfort. At his last visit a few days ago he was in excellent condition, having gained about 30 pounds (13.6 Kg). The foot remains healed (fig 10) and presents an excellent appearance.

CASE 8—M A, a man, aged 50, Jewish, born in Russia, first presented symptoms of thrombo-angiitis obliterans at the age of 41. At that time he showed migrating phlebitis of the legs and symptoms of intermittent claudication. When seen by me in May, 1930, he presented foul gangrenous ulcerations, involving the toe and dorsum of the left foot. The oscillometric index at the left ankle was 1.0. The pain was severe and the patient had lost considerable weight. Treatment was instituted with the usual routine and six months later the foot was completely healed with the exception of a pin-point opening, which has since healed. Spontaneous amputation of all toes occurred.

The fairly rapid healing of this extensive ulceration may perhaps be explained by the oscillometric index of 1.0, which signifies the establishment of good collateral circulation in the extremity. The patient has gained weight and is back at his usual occupation of storekeeper. He can walk long distances and does not require a special shoe.

CASE 9—F W, a man, aged 42, a Russian, not Jewish, consulted me in September, 1929, because of a gangrenous ulcer of the dorsum of the left big toe which he had had for the past eight months (fig 11). This was a typical instance of thrombo-angiitis obliterans, with a history of migrating phlebitis, heavy smoking and intermittent claudication. The oscillometric index at the left ankle was 0.3. The patient refused to remain in bed and received ambulatory treatment. This, no doubt, accounts for the fact that a period of one year was required to secure complete healing of the ulcer (fig 12). The usual local treatment was applied in addition to the intravenous

Fig 7 (case 3)—Complete healing of stump after sloughing

injection of 2 per cent sodium chloride solution three times a week.

CASE 10—G K, a man, aged 34, an American of German extraction, not Jewish, first showed symptoms of thrombo-angitis obliterans at the age of 29. For the next few years he had recurrent attacks of migrating phlebitis of both legs. He had been smoking about twenty cigars a day since boyhood. Six weeks prior to my first visit, in January, 1932, the patient had sustained an abrasion of the left middle toe. Within a few days an ulcer formed at the site of the injury, followed after a short time by gangrene of the major portion of the toe. The pain became intolerable and local physicians advised amputation of the leg as the only means of relief. This advice was, of course, not followed, and the patient placed himself under my care. He was ordered to bed with his legs in the horizontal position. Smoking was discontinued and intravenous injections of 5 per cent sodium chloride solution were started. The gangrenous, sloughing toe was irrigated with chloramine solution and a soothing ointment was applied liberally. The pain was relieved within six hours and the patient was able to sleep for the first time in five weeks without the use of any opiate. A line of demarcation was soon established, the gangrenous portion of the toe sloughed off, and six months after the treatment was started complete healing had occurred (fig 13). At present the patient is working and can walk long distances without intermittent claudication. He has gained about 20 pounds (9 Kg). The oscillographic index remains 0 at the left ankle.

Fig 8 (case 5)—Gangrenous ulcer of left heel

In spite of intensive treatment, gangrene of varying degree developed in all toes of the right foot. Irregular lines of demarcation soon formed, and after a total period of eight months the foot was completely healed. At present the patient has resumed his regular occupation of plumbing and has gained about 30 pounds (13.6 Kg). The usual treatment was carried out except for the use of 2 per cent sodium chloride solution instead of 5 per cent. This change was necessary because of the venous thromboses induced by the stronger solutions. During the entire course of treatment the intravenous injections were given by way of the external jugular vein. This was necessitated by the lack of suitable veins in the arms. Contrary to popular opinion there is no danger in using the external jugular vein for intravenous injections.

CASE 12—M MacM, a man, aged 49, an American of Scotch descent not Jewish first noticed migrating phlebitis of the right leg in 1929 at the age of 44. He had been treated for syphilis twenty-six years previously, but repeated Wassermann tests since then were negative. About a year prior to my first examination a gangrenous ulcer of the distal part of the right big toe had developed (fig 14). The oscillographic index at the right ankle was 0. The ulcer was painful interfering with sleep and the patient had lost considerable weight because of his rigid adherence to a salt-free diet. This diet had been prescribed by a local physician because of the possible presence of arteriosclerosis. Considerable improvement and

gain in weight were noted when the diet was discontinued. Three months after the institution of routine treatment the ulcer was completely healed. The patient can walk long distances without discomfort. The presence of syphilis in this case probably exerted no influence on the course of the disease.

DETAILS OF TREATMENT

Because of the great importance of the minute details of therapy in the handling of these cases, I shall describe carefully all the points I have learned in the past ten years which I believe are of value in the

Fig 9 (case 5)—Appearance after nine months

successful healing of gangrene. It must be remembered that no single remedy or procedure is advocated in these cases. It is, on the contrary, the intelligent combination of various fundamental factors that I wish to emphasize in this discussion.

1 *Rest in Bed*—Physiologic rest is well recognized in surgery as an essential factor in the healing of wounds and ulcers. It is equally important in the treatment of thrombo-angitis obliterans with ulceration or gangrene. It is of additional importance in these cases that the principle of physiologic rest be extended to the lower extremities by maintaining these members constantly in the horizontal position. I have often been astonished at the appearance of some cases of gangrene when the physician in charge had allowed, and in some instances ordered the patient to sit either on the edge of the bed or in a chair, day and night, in order to obtain some relief of pain. As a result of this continued

Fig 10 (case 7)—Appearance of foot after healing

dependence of the lower limbs, the venous and lymphatic return is obstructed and an intense edema of the feet, legs and thighs is produced. In some instances this edema has been wrongly interpreted as a sign of deep seated infection and ill advised amputations have been hurriedly performed. The maintenance of such swollen extremities in the horizontal position for twenty-four hours or more causes a rapid disappearance of the edema. This positional swelling, even if confined to a single toe, retards the healing process and may be the only factor responsible for the chronicity of

many ulcers. I feel sure that this is one of the reasons for the unsuccessful results obtained in outpatient departments in which ambulatory treatment of these cases is the rule. A striking instance of this observation is evident in a case seen recently wherein the patient had been shopping around at various clinics in the city over a period of two years in a vain attempt to heal a small ulcer of the toe. I insisted that he remain in bed and within two weeks the ulcer was completely healed. Such cases are common and illustrate the importance of the maintenance of the horizontal position of the extremities throughout all phases of ulceration and gangrene.

2 Smoking—Michels⁵ in 1909, was apparently the first to observe the importance of smoking as an aggravating factor in thrombo-angitis obliterans. He named the disease "nikotin-arteritis" and emphasized the importance of prohibition of smoking in the successful treatment of these cases. Schlesinger,⁶ in 1913 reported clinical improvement in two cases of thrombo-angitis obliterans after complete cessation of smoking. Whether the bad effects are due to the vasoconstricting action of nicotine or to tobacco sensitization of the endothelium of the arteries and veins, as suggested by Sulzberger,⁷ is as yet uncertain. Clinical experience has convinced me that smoking is unquestionably harmful in all stages of this disease.

Maddock and Collier⁸ have demonstrated, by skin temperature changes in the extremities the peripheral vasoconstrictor action of smoking. The clinical effects of smoking are demonstrable in all stages of thrombo-angitis obliterans. In cases without ulceration or gangrene, persistent smoking produces progressive intensification of symptoms. Walking becomes increasingly painful and difficult. The toes and feet become colder, even in warm weather. Crops of migrating

in these stages, is intensified to such an extent that even the most potent local anesthetic ointments become ineffectual. A healthy granulating ulcer may change its appearance over night if smoking is resumed. A demarcating area of gangrene may spread with alarming rapidity with the resumption of smoking. On the other hand, a very favorable influence is exerted by complete cessation of the use of tobacco. There is usually a spectacular decrease in the intensity of pain. This includes the so-called rest pain as well as the local burning pain present in ulcerated or gangrenous areas.

Fig. 13 (case 10)—Healing after gangrenous portion of foot had sloughed off.

Healing of ulcers is favored and the establishment of a line of demarcation in gangrene is encouraged. From these clinical facts it is essential to learn the importance of "no smoking" in the treatment of this disease.

3 Intravenous Saline Injections—Mavesum⁹ in 1911 while engaged in the study of blood viscosity, observed an increase in the viscosity of the blood in cases of thrombo-angitis obliterans. Koga,¹⁰ an assistant of Ito in the surgical clinic at Kyoto, Japan, was the first in 1913 to introduce intravenous therapy in the treatment of thrombo-angitis obliterans in the attempt to lower the blood viscosity and thus improve the circulation in the extremities. Koga used physiologic solution of sodium chloride in some of his cases and Ringer's solution in others. He administered 400 cc of solution daily and noted definite and striking clinical improvement in all cases treated. Willy Meyer¹¹ in 1916 was the first American investigator to adopt Koga's method of treatment. Meyer at first used physiologic solution of sodium chloride by hypodermoclysis but later changed to Ringer's solution. He also noted remarkable improvement in his treated patients. Ginsburg¹² in 1917 suggested the use of 2 per cent sodium citrate solution intravenously. Steel¹³ in 1921 reported good results with the use of this solution. Jablons¹⁴ added isotonic salts to the citrate solution to diminish its toxicity and was favorably impressed with the results. Silbert,¹⁵ in 1926 recom-

Fig. 11 (case 9)—Gangrenous ulcer on big toe.

Fig. 12 (case 9)—Ulcer completely healed.

phlebitis appear with greater frequency. Ulceration or gangrene usually ends the picture in these cases in which smoking is persistent, and thus the time-worn mistaken idea is created that the disease is progressive and hopeless.

In the ulcerative or gangrenous phases of the malady, smoking produces its most destructive effects. Pain,

mended the use of hypertonic (5 per cent) sodium chloride solution. I have found that in some cases it is preferable to employ a solution of less hypertonicity in order to avoid annoying thromboses in the veins of the arm at the site of injection. In such cases I have reduced the sodium chloride solution to 3 or 2 per cent. Elderly patients are also best treated with the weaker concentrations. In any case, the solution must be hypertonic.

The action of intravenous injections of hypertonic salt solutions has been the subject of study in my clinic with the assistance of Drs. Weichsel and Ferber. We have made oscillometric tracings of the extremities in cases of thrombo-angitis obliterans before and after the intravenous injections. This work will be reported in greater detail in a future communication. At this time I can say that a consistent increase in pulse amplitude and pressure was observed following the intravenous injections. Figure 15 shows an oscillometric tracing of the peripheral pulse in a case of thrombo-angitis obliterans before and after an intravenous injection of 300 cc of hypertonic sodium chloride solution. The resultant increase in pulse amplitude undoubtedly accounts for the beneficial effects of this form of therapy.

Saline therapy should be started as soon as the diagnosis of thrombo-angitis obliterans is made. It is not to be considered as a specific for the disease but as a mechanical aid in the enhancement of collateral circulation in the extremities. Three hundred cubic centimeters is given every other day until gangrene and ulceration are healed. Later the injections may be given at longer intervals, depending on the severity of the case. In cases without ulceration, clinical improvement is noted in improved nail growth, increased warmth of the extremities and cessation of intermittent claudication.

4 Local Treatment of Ulceration and Gangrene—Success in the treatment of ulceration and gangrene in this disease requires adherence at all times to correct surgical principles. It must be remembered that, since the gangrene has formed only because the blood supply to that particular area has become insufficient, a line of demarcation will form at a point at which the blood supply is adequate. The eventual line is usually clear cut and marks the site of spontaneous amputation of

Fig. 14 (case 12)—Gangrenous ulcer on toe

dead tissue whether it be soft parts alone, or soft parts plus tendons, bones or other deep structures.

The aim of local treatment is to aid in the development of the line of demarcation, to maintain the dead and dying tissue as aseptic as possible and to control the pain. At this point it seems advisable to disregard the traditional distinction between "dry" and "wet" gangrene. In my experience, all forms of gangrene in thrombo-angitis obliterans are "wet." They are all masses of dead infected tissue that should be encouraged to slough off as soon as possible. Careful surgical attention to the sloughing tissues is extremely important.

At the first sign of gangrene, active measures for cleanliness of the parts and relief of pain should be instituted. Foot baths of a mild antiseptic solution such as 0.5 per cent chloramine or boric acid are most beneficial. The baths are usually given once a day or more often in severe cases. The parts should be immersed for ten minutes or more. Following the bath,

Fig. 15—Oscillometric tracing at ankle level to show increase in amplitude of pulse following intravenous injection of hypertonic sodium chloride solution

an anesthetic ointment is liberally applied to all exposed areas. Considerable patience is necessary in the selection of the proper ointment for each case. The following, alone or in various combinations, have proved satisfactory: Ethylaminobenzoate ointment, 10 per cent; nupercaine ointment, 1 per cent; camphor-phenol ointment, 1 per cent of each. Following the application of the ointment, a protective gauze dressing is applied. Dressings may be changed once or twice a day, depending on the severity of the case.

The control of pain in these cases is of the greatest importance and merits careful study. It should never serve as an excuse for an amputation. The most severe pain is encountered in the acute stage of spreading gangrene. It is a constant, deep agonizing pain caused by dying tissue and subsides usually after the line of demarcation has been established. In other words, this most severe pain usually lasts only a few weeks. For this reason it is essential that the physician does not "lose his head" and advise an unnecessary amputation. He should, on the contrary, attempt to alleviate the pain until the acute process is over. The liberal application of anesthetic ointments to the dying tissues is helpful. In some cases the temporary administration of small doses of opiates may be necessary. This is the exception rather than the rule. In my cases I have rarely found it necessary to use anything stronger than codeine. Patient 3 never received or required more than 1 gram (0.65 Gm.) of codeine in twenty-four hours.

In this acute stage there is a great temptation to resort to peripheral nerve section for the relief of pain. In my opinion this procedure is unnecessary and dangerous. The anesthesia of the foot that is obtained after this operation is of long duration and may be the cause of future serious trouble. The patient may burn

or traumatize his foot because of the loss of protective sensation. The possibility of later trophic ulcers must also be considered.

Another type of pain is sometimes encountered in the healing stages of ulceration. It is described as a burning sensation out of all proportion to the size of the ulcer. This pain usually is easily controlled by the application of an anesthetic ointment to the exposed parts and by the cessation of smoking. It is gratifying to observe the instant relief one can give these patients after they have been suffering for months. Rest in bed is also necessary in these cases.

In the granulating stages of ulceration it is sometimes possible to apply wet dressings of boric acid or chloramine solution and thus stimulate granulation and epithelization. If these are too painful, soothing ointments, such as boric acid or chloramine surgical cream may be applied.

Sympathectomy and Ganglionectomy.—In my experience these operations have no place whatever in the treatment of gangrene or in any phase of thrombo-angitis obliterans. The spastic element in this disease plays such a minor role as to be negligible in the consideration of therapy. As is apparent from the results shown in this communication, much more can be accomplished by the employment of comparatively simple procedures based on recognized surgical principles. The sponsors of the various sympathetic operations have reported no cases of massive gangrene healed by this method. The minor cases of small ulcers or small areas of gangrene that have been reported as healed after such operative procedures have, in my opinion, healed only because the patients have been confined to bed during the postoperative period. Furthermore, the risk attached to the operation of lumbar sympathectomy is unwarranted in any case of thrombo-angitis obliterans.

SUMMARY

Additional experience with the treatment of gangrene in thrombo-angitis obliterans reemphasizes the fact that the process is self limited. The only indication for amputation in this disease is total destruction of the foot, so that a weight-bearing stump is unattainable.

In twelve cases of gangrene and ulceration here reported, healing was accomplished by simple measures, without the use of any operative procedure. Sympathectomy is unnecessary in the treatment of thrombo-angitis obliterans.

Treatment consists of a careful coordination of the following factors: (1) rest in bed, (2) prohibition of smoking, (3) intravenous injections of hypertonic saline solution and (4) surgical cleanliness of ulceration and of gangrenous areas.

151 East Eighty-Third Street

Signs of Vitamin A Deficiency.—The signs of gross deficiency of vitamin A in human beings most frequently recognized are xerophthalmia and acquired night-blindness, which are not uncommonly associated in the same individual. Such cases are met with in our own country, and it is of importance that this fact should be recognized because they respond very quickly to appropriate treatment in their early stages and can be completely cured. There is also evidence that deprivation of vitamin A leads to a variety of nervous lesions caused by degeneration of peripheral nerves and tracts in the central nervous system. Such degenerations are intensified at least in experimental animals by certain common food principles, of which one is a substance of unknown composition present in the germ of cereals—Colwell, S. J. *Vitamins in Clinical Medicine, Practitioner* 132:15 (Jan.) 1934.

GENERALIZED ANGIOMATOSIS (TELANGIECTASIA)

JOHN F. MADDEN, MD

ST. LOUIS

Generalized telangiectasia may be an important sign of constitutional disease or the small lesions may be only blemishes of cosmetic importance. During the past year a number of cases of generalized angiomatosis were referred to the dermatologic division for an opinion and the information gained from the investigation of these cases has served as the basis for this report.

The cases of hereditary hemorrhagic telangiectasia are by far the more important because of a higher percentage of fatal terminations. The condition may be defined as a hereditary disease of the small blood vessels characterized by the formation of multiple permanent localized dilatations of the capillaries and venules which may give rise to apparently spontaneous and often recurrent hemorrhages. The telangiectasia has been most frequently noted in the skin of the face and in the mucosa of the mouth and nose. The hemorrhages occur most commonly in the form of recurrent epistaxis.

The angiomatosis associated with constitutional disease is not serious in itself although the disease which it accompanies may cause death.

The nevus type of telangiectasia may be the site of hemorrhage but this is almost always secondary to trauma. The patients of this group are not related to angiomatosis.

HISTORY

The literature on angiomatosis is quite extensive, but most of it is concerned with the hereditary hemorrhagic type. For a more detailed bibliography the reader is referred to Goldstein's article published in 1932.

Hereditary hemorrhagic telangiectasia was first reported by Sutton¹ in 1864 as internal hemorrhages and telangiectasias of the skin. Erasmus Wilson² in 1869 called the condition eruptive angiomatosis. Charri³ in 1883 regarded it as a hemophilia of slight degree. Rendu⁴ in 1896 as juvenile hereditary epistaxis associated with multiple hemorrhagic telangiectasias of the skin and mucous membranes. Ullmann⁵ in 1900, as angiomatosis, and Osler⁶ in 1901 as a familial form of recurring epistaxis associated with multiple telangiectasias of the skin and mucous membranes.

In 1865 hereditary epistaxis was described in five generations of one family by Babington.⁷ He made no mention of lesions of the skin in his patients.

Eigler⁸ regarded generalized angiomatosis as a "system disease" of vascular-forming mesenchyme and

thought that it was parallel with tumor-like disease of the blood-forming organs. He stated that the disease did not occur through endothelial branching, but rose from perivascular mesenchymal tissue with slow new vessel formation.

Curschmann⁹ believed in the thromboembolic origin of hereditary hemorrhagic telangiectasia. He considered familial epistaxis as a hemorrhagic diathesis because of the familial character, the duration throughout the patient's entire life, and its pernicious character. He called the disease pseudohemophilia and stated that familial epistaxis is seen in female members of hemophilic families (abortive).

Ebert,¹⁰ Pautrier¹¹ and Weber have described cases under the following respective titles: *livedo reticularis*, a new form of cicatricial atrophic angiomatous telangiectasia and telangiectasia macularis eruptiva perstans. Although similar in general character to my cases, these conditions are not closely enough related to be discussed in detail here.

The chief contributors to the literature have been Becker,¹² Fitz-Hugh, Jr.,¹³ Goldstein,¹⁴ Osler,¹⁵ Ullmann¹⁶ and Weber.¹⁷

CLASSIFICATION

In classifying multiple telangiectasia, the following subdivisions are quite distinct although there are numerous borderline cases which might fall in no one group.

1 *Primary Telangiectasia*—This class can include hereditary hemorrhagic telangiectasia, certain cases of familial hematuria and epistaxis, not due to disease of the blood, in which no obvious telangiectasias have been seen, also familial cases of telangiectasia without hemorrhage and certain possible examples of atavism without a family history.

2 *Secondary Telangiectasia*—This group includes generalized telangiectasia dependent on constitutional diseases, such as disease of the liver and leukemia and angiomatosis occurring in pregnancy.

All of the types of generalized telangiectasia under Becker's etiologic classification are included here: those of an infectious origin such as are seen in syphilis,

those of endocrinous origin as seen in dysfunction of the endocrine glands, especially the thyroid and pituitary glands, those found in cardiovascular disease such as myocarditis and the angiomatosis occurring in diseases affecting the nervous system, such as syphilis and lead poisoning.

Lanceplaine's¹⁸ three classes based on his pathologic-anatomic classification also are included in this subdivision: the neurogenous type presumably caused by damage to the vasomotor nerves, the mechanical type seen when an inflammatory process causes narrowing of the lumen of the vessel by endarteritis or compression caused by perivascular fibrosis, and the angiomatosis caused by toxic factors which are thought to destroy the strength of the wall of the vessel. Heredity plays no role in this type.

3 *Nevoid Telangiectasia*—This type may be present at birth, it may appear early in life, or it may occur even in old age. Generalized, punctiform, capillary ectasias which occur in people beyond middle life and spider telangiectasias which appear at any age may be included in this subdivision.

Weber summed up the difficulties in classification in the following manner:

First, in some cases lesions that have developed ("been acquired") in adult life are associated with more or less similar lesions that were present at birth and are therefore vascular nevi.

Second, lesions that morphologically belong to different classes of telangiectasia and hemangiomas may occur simultaneously in the same person.

Third, it is probable that lesions caused or excited by the same factors (traumatic, toxic) may differ structurally or in form (morphologically) in different persons according to the inherited constitutional predisposition, and that different causal factors may sometimes give rise to the same structural and morphologic type of lesion.

The exact cause of generalized angiomatosis is speculative and not based on fact. Many authors expressed widely divergent opinions. Although it is often difficult to separate the constitutional factors from the exciting factors, both must exist in every case of generalized angiomatosis. The underlying constitutional factor of heredity is present in most cases of primary angiomatosis in addition to various exciting factors such as trauma, irritation and congestion. The patients with other types of angiomatosis also must have some hidden constitutional predisposition as well as the more apparent exciting cause.

These theories are not only borne out in generalized angiomatosis, but apparently hold true in localized telangiectasia as well.

REPORT OF CASES

CASE 1—*Hereditary hemorrhagic telangiectasia illustrating the primary type of generalized angiomatosis.*

History—Mrs M. T. aged 64 was seen in the dermatologic department because of lesions on the skin and tongue. The eruption had been present as long as she could remember. New lesions appeared from time to time but none had disappeared. The eruption was generalized but there were only a few scattered lesions below the neck.

The lesions were located particularly on the face and mucous membranes of the nose and mouth. The telangiectasias become more numerous near the midline of the face and were most marked on the nose lips and malar eminences. There was an extensive telangiectatic network covering the nasal septum.

The tongue was larger than normal and was painful on palpation. The entire surface was beefy red and was studded at frequent intervals with telangiectatic vessels varying in size from that of a pinhead to that of a pea. The buccal mucous membrane and pharynx were also involved. The lesions consisted of superficial telangiectasias occurring singly and in groups.

Both sides of the nasal septum were almost covered with telangiectasias. The size of a single lesion varied from that of a millet seed to that of a split pea. The lesions were dark red. The color disappeared under diascopic pressure except where there had been recent hemorrhage. There was an accompanying pigmentation around the lesions that had bled recently.

The patient had complained of severe nosebleeds at frequent intervals for years. The hemorrhages seemed to start spontaneously and often lasted for from fifteen minutes to an hour. There were times when she had from ten to fifteen nasal hemorrhages in one day. The bleeding usually stopped spontaneously or on the application of pressure. It was never neces-

Fig. 1 (case 1)—Hereditary hemorrhagic telangiectasia showing lesions on the face.

sary to call a physician to stop a hemorrhage. The epistaxis had become more frequent in recent years.

The patient had a burning sensation in her tongue which varied in severity from time to time. Occasionally the tongue became swollen and acutely painful. The pain and swelling subsided gradually. She thought that hemorrhage followed accidental biting of the tongue.

The patient noticed blood streaked sputum almost every time she coughed.

Her past health had been good except for a toxic goiter, which was removed surgically. The rest of the physical examination gave essentially negative results. The patient apparently had not been seriously affected by the disease itself.

She stated that her father and one sister had frequent nosebleeds and similar spots on the face. One brother died of epilepsy. The patient had eight children. One daughter had had the same type of eruption and frequent nasal hemorrhages since childhood.

Laboratory Examination—Examination of the blood showed hemoglobin 97 per cent, red cells 4,900,000, white cells 5,650. A differential count showed polymorphonuclear neutrophils 38 per cent, lymphocytes 58 per cent, and monocytes 4 per cent, platelets 145,000. The bleeding time was

two minutes and fifty seconds, the clotting time, two minutes, and twenty seconds. The Wassermann and Mantoux tests of the blood were negative.

Biopsy showed only dilated blood vessels and new blood vessel formation in the upper part of the cutis without any change of the overlying epidermis or surrounding connective tissue. There was complete absence of infiltrate.

CASE 2—*Generalized telangiectasia occurring in a patient with chronic myelogenous leukemia, illustrating the secondary type of generalized angiomatosis.*

Miss N. P., aged 20, a schoolgirl, was seen by the staff of the dermatologic department because of a generalized redness of the skin. Her mother stated that she first noticed telangiectasias on the right forearm when the patient was 7 years old (1919). The eruption progressed slowly, apparently spreading from the affected part of the skin. In February, 1932, the right arm, the face, the neck, and the right side of the thorax were involved. During the past year the eruption had spread much more rapidly and at the time of examination involved most of the cutaneous surface. The accompanying leukemia had been effectively controlled, but the telangiectasia continued to increase.

The eruption was a generalized, fine network of telangiectasias. The lesions were larger and more marked on the neck, face, and right arm. The mucous membranes were not involved. The telangiectasias disappeared completely under diascopic pressure. The size of the lesions varied from barely discernible lines to those the size of a coarse horsehair. The new, fine telangiectasias were closely knit, while the old, larger lesions formed a looser meshwork. They did not disappear spontaneously but continued to grow in size and number. The color was the bright red of arterial blood. There had never been hemorrhages from any of the lesions. The telangiectasias did not appear more rapidly or in greater numbers in the areas that received roentgen treatments.

The rest of the physical examination was essentially irrelevant.

The family history was negative for any disease of the blood or similar eruption.

Laboratory Examination—On Feb. 27, 1932, examination of the blood showed hemoglobin 38 per cent, white cells 750,000, red cells 1,990,000. A differential count showed polymorphonuclear neutrophils 27 per cent, promyelocytes 40 per cent, myelocytes 13 per cent, metamyelocytes 7 per cent, monocytes 3 per cent, lymphocytes 3 per cent, eosinophils 5 per cent, basophils 1 per cent, and platelets 472,000.

In order to demonstrate how well the leukemia was controlled by roentgen treatment, the blood count made on September 14 showed hemoglobin 89 per cent, white cells 13,000, red cells 4,050,000, platelets 210,000. Fragility began at 0.44 and was complete at 0.38. The bleeding time was three minutes, the clotting time four minutes. The Wassermann and Mantoux tests of the blood were negative.

Biopsy showed the same findings that were noted in case 1.

CASE 3—*Generalized telangiectasia, illustrating the new type of generalized angiomatosis.*

Mr. W. W., aged 23, a senior medical student at the University of Minnesota, consulted the staff of the dermatologic department regarding what he called hemorrhages in the skin. The patient first noticed an irregular patch of blood vessels appearing on the lateral surface of the right hip when he was about 12 years of age. During the next five years new lesions appeared around the umbilicus on the back on both thighs and over the knees. The eruption became more marked, until most of the surface of the skin was involved.

There were lesions on the palpebral and bulbar conjunctiva, the mucous membrane of the mouth, and the glans penis. The patient thought that the eruption had remained stationary for about two years. None of the lesions had disappeared or enlarged after they had been discovered.

The lesions were generalized but they were far more numerous on the genitalia and thighs about the umbilicus and over the scapulae. The telangiectasias were nearly all discrete and dark red. The dilated vessels were uniformly about the size of the head of a common pin. The lesions disappeared

under diascopy, and there had been no associated hemorrhage. Numerous, various sized, brown, macular nevi were scattered over the entire body. There was an irregular, dark brown elevated, solid, hairy nevus about 1 inch (2.5 cm) wide and 3 inches (7.6 cm) long to the right of the twelfth dorsal spine. A marked left-sided varicocele was present.

The patient had complained of frequent headaches since childhood. He was partially color blind.

The rest of the examination, including neurologic and ophthalmologic examinations, gave negative findings. There was no history of a similar eruption or any cutaneous or vascular disease in the family for three generations.

Laboratory Examinations—X-ray pictures of the skull showed a possible slight increase in intracranial pressure and some erosions of the inner table of the skull. A calcified pineal gland was shown directly in the midline. Head¹⁰ reported two cases of generalized angiomas which he thought were associated with dyspituitarism. The pictures of his cases resembled this patient very much. The calcified pineal gland found in this case and the dyspituitarism noted in Head's patients were probably coincidental findings. The reader is urged to review Head's article, because the colored plates are exceptionally good.

Examination of the blood showed hemoglobin, 80 per cent, red cells, 5,300,000, white cells, 7,600. A differential count showed polymorphonuclear neutrophils, 58 per cent, lymphocytes, 36 per cent, monocytes, 6 per cent, and platelets, 340,000.

Fig. 2 (case 3)—Nevoid type of generalized angiomas showing grouping of telangiectases and association with pigmented nevi.

The bleeding time was one minute and thirty seconds, the clotting time 5 minutes. Fragility began at 0.44 and was complete at 0.36. The Wassermann and Mantoux tests of the blood were negative.

The microscopic study revealed the same findings that were noted in case 1.

CASE 4 (Dr H E Michelson's case)—Generalized telangiectasia occurring in a pregnant woman, illustrating the secondary type of generalized angiomas.

Mrs M M, aged 30, consulted Dr Michelson regarding a generalized eruption. She stated that she had had a similar, but less marked, eruption during her one previous pregnancy.

Fig. 3 (case 3)—Nevoid type of generalized angiomas showing telangiectases in the bulbar conjunctiva.

three years prior to examination. Lesions began to appear about the third month of pregnancy. They increased in number up to the seventh month. After that no new lesions appeared. They were scattered over the entire surface of the body, but the mucous membranes were not involved. The lesions were discrete and showed no tendency toward configuration. The telangiectases were of the spiderweb type, showing a central, pinhead-sized dilatation with numerous spokelike vessels radiating from it. The color was bright red and disappeared under diascopic pressure. There was no hemorrhage. All the lesions disappeared about two months after pregnancy was terminated.

The pregnancy was normal in all respects. The blood findings, the Wassermann test and all other laboratory tests were normal. The baby was normal. There was no history of a similar eruption in any members of the family.

CASE 5 (Dr H E Michelson's case)—Generalized telangiectasia occurring in a pregnant woman, illustrating the secondary type of angiomas.

Mrs W A, aged 28, showed an eruption similar to that in case 4, except that the lesions appeared during the fifth month of her first pregnancy.

This is undoubtedly a more common finding than the literature would indicate. Gougerot and Meyer²⁰ reported a similar case recently in the French bulletin of dermatology.

SIGNS AND SYMPTOMS

Heridity—This factor is noted in most cases of the primary type of angiomas, but does not occur in the other groups. There are some cases which have all the classic signs and symptoms of hereditary hemorrhagic telangiectasia except that no hereditary factor can be found. Fitz-Hugh explained this on the basis of atavism, the inheritance of a characteristic or disease from remote but not from the more immediate, ancestors. A typical family history can be obtained in the great majority of cases of hereditary hemorrhagic telangiectasia. Several members of each family for as

²⁰ Gougerot M M and Meyer Jean. Telangiectases periodiques paroxysmiques et familiales apparaissant et disparaissant avec la grossesse. Bull. Soc. franc. de dermat. et syph. 26:1032 (Nov.) 1929.

many generations as can be traced are often involved. Both sexes transmit the disease, and both are equally affected.

Telangiectasia—This, of course, is present in all types of angiomas. The number of telangiectatic vessels in the skin is no indication of the extent of the lesions in other organs of the body.

Pressure is an important factor in all vascular dilatations. This force is opposed by the elastic and contractile character of the vessel and the resistance of the surrounding tissue. Virchow²¹ stated that any chronic inflammation can produce dilatation and enlargement of vessels. The changes are not limited to any certain type of vessel and are not characteristic of inflammation but can be produced by most different disease processes. All parts of the vascular system undergo similar changes in ectasia. General and partial aneurysmal and varicose dilatation takes place in both large and small vessels. Any chronic dilatation produces changes in the wall of the vessel. All these processes belong to no specific change but are the result of definite disturbances of nutrition. No studies with the capillary microscope were made to determine whether the ectasias were arterial or venous.

Bonmer²² demonstrated stereoscopic pictures of capillaries taken with a new capillary camera in a case of hereditary hemorrhagic telangiectasia shown before a Berlin dermatologic society in December, 1932. Further work along this line may be of great value in determining the exact nature of the telangiectasias.

Ullmann regarded generalized angiomas as a pathologic character chiefly of the connective tissue elements of the skin and mucous membranes producing multiple telangiectasias spontaneously or following irritation. He found considerable endothelial proliferation in the numerous new vessels. The microscopic picture differs from that of endothelioma and endothelial sarcoma in that there are no intravascular papillomas. There is no unusual increase in the layers of cells in the endothelium of the new vessels. The connective tissue in the cutis is normal. Angiomas are not a new growth but is a passive process.

In hereditary hemorrhagic telangiectasia the lesions are usually present at birth but they become more numerous and more noticeable as the patient grows older. In mild cases the eruption often escapes the patient's notice until sometime during the second decade of life. The lesions are always multiple and are usually more numerous in the skin of the face and the mucous membranes of the mouth and nose. They may occur in any organ of the body. The telangiectasias generally grow to the size of a millet seed or that of a split pea and remain stationary. The lesions are permanent and are not obliterated even after repeated hemorrhages. The telangiectasia disappears under diascopic pressure.

Lindau²³ described cases in which trigeminal nevi, homolateral pial angiomas showing calcification in roentgenograms and a unilateral glaucoma form a characteristic syndrome. The disease is often seen in children, and in a few cases there is a family history. Calcareous deposits may be in the walls of the angiectatic vessels or in their thrombosed channels, or they may be extravascular and a result of hemorrhages or

thrombotic necroses. The relationship between hereditary hemorrhagic telangiectasia and familial cases of Lindau's syndrome is speculative.

The secondary type of telangiectasias associated with constitutional disease has no site of predilection. The mucous membranes are less apt to be involved in this group. The lesions may appear as discrete points or as a general telangiectatic veil spread over the entire skin. Small, spider telangiectasias are especially associated with chronic jaundice. The lesions are bright red and completely disappear under diascopic pressure. They usually become more numerous as the accompanying constitutional disease progresses. The telangiectasias generally disappear when the associated disease is cured. This is particularly true in chronic jaundice and pregnancy. Because leukemia is a fatal disease, the associated telangiectasias are permanent.

The telangiectasias in the nevus group may appear on any part of the body. The mucous membranes are commonly involved. The lesions are always discrete but are often seen in groups. Various types of nevi are frequently associated with these telangiectasias. The lesions are permanent and increase in number as the patient grows older. They are usually about the size of the head of a common pin and do not enlarge after that size has been reached. The lesions disappear on pressure and vary in color from bright to dark red.

Hemorrhage—This is one of the most important symptoms in the primary type. There seems to be very little evidence favoring the view that there is an underlying hemorrhagic diathesis or blood dyscrasia causing the hemorrhages. The bleeding apparently may be spontaneous or may be caused by trauma, irritation or mechanical or vasomotor congestion. Hemorrhages may appear at any time in the course of hereditary hemorrhagic telangiectasia but it is generally agreed that the hemorrhages become progressively more severe and occur more frequently as the patient's age advances. Hemorrhages can take place in any organ of the body but most commonly occur as recurrent epistaxis. Bleeding from the nose, lips, tongue, tonsils, pharynx, larynx and gastro-enteric tract, uterine or vaginal bleeding, hematuria, hemoptysis and rectal intra-ocular, cerebral or meningeal hemorrhage have been reported. The bleeding may appear at several points in one particular part of the body at the same time but it is unusual for two distinct regions to have simultaneous hemorrhages. There is no subcutaneous oozing and the hemorrhage usually appears at the most superficial point of the telangiectasia. The bleeding is often more steady and regular than sudden and spurting. The size of the hemorrhage depends chiefly on the extent of injury to the vessel. The usual history is that of repeated small hemorrhages but occasionally single hemorrhages result in death. The bleeding can always be stopped if the source can be found and is accessible.

Certain cases of "essential hematuria" seem to be examples of primary angiomas. Urologists have reported a number of cases of essential hematuria found at operation to be caused by small varices and angiomas of the renal pelvis. The group of cases of "hereditary hematuria" reported by Aitken²⁴ and Conner and Bumpus²⁵ of the Mayo Clinic and Pearson²⁶

probably are examples of hereditary hemorrhagic telangiectasia

Hemophilia has been confused with hereditary hemorrhagic telangiectasia to such an extent that some authors have called the latter condition "pseudohemophilia" and "hemophilia of slight degree." Hemophilia is confined to the male sex and transmitted by the female alone. Hemophilic persons bleed at any injured point from apparently normal tissue while the other patients' hemorrhages are confined to the telangiectatic points. The coagulation time is delayed in hemophilia and normal in primary angiomatosis.

The blood platelets are greatly reduced in purpuric hemorrhagic telangiectasia and normal in hereditary hemorrhagic telangiectasia. The telangiectasias disappear under diascopic pressure, while purpuric spots do not.

Hemorrhage is rare in the secondary or nevus types of angiomatosis. When it occurs, it is almost always caused by direct trauma to the telangiectatic vessel. There is no spontaneous bleeding and no history of repeated hemorrhages. The amount, size and treatment of each hemorrhage depend on the factors mentioned, but when hemorrhage occurs in the secondary type associated with chronic jaundice and diseases of the liver, it may be more difficult to stop.

Blood—The findings are normal in the primary types of generalized angiomatosis except when there is a secondary anemia from repeated hemorrhages. There is no temporary or transitory thrombocytopenia or qualitative disturbance of the blood such as one would expect to find where there apparently is spontaneous bleeding. The changes in the blood in the secondary group are those found in the associated disease such as leukemia. One of the most striking features in a case of polycythemia vera seen at the University Hospital in March 1933, was the intense mottled purplish color of the face and buccal mucosa associated with many telangiectatic points similar to the conditions emphasized by Gans.²⁷ Clough²⁸ stated that the discoloration of the skin may be the first sign of the disease and may antedate by years any actual discomfort. The individual vessels are distended and far more capillaries are patent and contain blood than in normal persons. The skin of the trunk is ordinarily free from telangiectasias. When the disease accompanying the telangiectasia has no changes in the blood, the blood findings are normal. The blood in the nevus type is normal.

Splenomegaly—Fitz-Hugh reported four cases of splenomegaly in patients with hereditary hemorrhagic telangiectasia. This association is rare in primary angiomatosis, it occurs in secondary angiomatosis only as a sign of the accompanying constitutional disease and it has not been noted in the nevus type. Fitz-Hugh thought that splenomegaly occurred relatively late in hereditary hemorrhagic telangiectasias and only in the more severe cases. In these cases splenomegaly follows repeated hemorrhages and probably is the result of long-standing stimulation and demands on a blood-forming organ.

The most important step in making a diagnosis is to classify properly a case in which angiomatosis is the presenting sign. After a case has been properly grouped the diagnosis is comparatively easy.

COMPLICATIONS AND PROGNOSIS

Complications are very rare in the secondary and nevus types of generalized angiomatosis, but they are common in the primary type. Nearly all of the complications are caused by hemorrhage. Death was caused by gastro-enteric hemorrhages (Osler) hemorrhages of the throat (Fitz-Hugh), epistaxis, convulsions from cerebral hemorrhage, intracranial hemorrhage and bleeding from other parts of the body in certain cases of hereditary hemorrhagic telangiectasia.

The prognosis in secondary and nevus angiomatosis is good. The prognosis in primary angiomatosis must be guarded, because a fatal hemorrhage or hemorrhages leading to a fatal complication may occur at any time. Four per cent of Fitz-Hugh's patients with hereditary hemorrhagic telangiectasia died of the disease itself.

TREATMENT

The treatment of the primary type of generalized telangiectasia deals with the prevention of hemorrhage and the stopping of immediate hemorrhage. The method of choice is actual cautery and if it is repeated often enough, all of the telangiectatic vessels can be destroyed. This is obviously impossible when certain parts of the body such as the meninges are involved. In such cases there is no known treatment. In the nevus and secondary types bleeding is rare. However, the usual methods of treatment, such as cautery or the application of pressure are effective in stopping the bleeding.

The use of calcium horse serum and the like presupposes an abnormality in the blood which does not exist. Hence these measures are of no value.

The cosmetic features of generalized angiomatosis cannot be disregarded. If the eruption is not too extensive the lesions on the face can be removed satisfactorily by actual cautery.

SUMMARY

1 Generalized angiomatosis is an important clinical sign, and patients with this condition should not be dismissed without a careful investigation.

2 A classification of types of generalized angiomatosis is offered. It is based on the relationship of the condition to constitutional disease, hereditary factors or a purely nevus source.

3 Cases from all three groups are reported.

ABSTRACT OF DISCUSSION

DR MICHAEL H. EBERT, Chicago. Generalized telangiectasia, like purpura, urticaria and multiple erythema, is often simply a manifestation of some deeper disease, and it requires a thorough investigation to determine where any particular case should be placed. The etiology is still speculative but one point Dr. Madden brought out is very interesting. In cases of generalized telangiectasia due to some form of intoxication in this particular instance a pregnancy the telangiectasia disappeared when the cause of the intoxication was removed. I wonder whether Dr. Madden made histologic studies in that case and how he explains the disappearance of new blood vessels. One can conceive of telangiectasia disappearing with tonus restored to the vessels but I wonder how the new formed vessels were absorbed.

DR S. WILLIAM BECKER, Chicago. The term angiomatosis versus telangiectasia might give rise to some misunderstanding because other cases of generalized angiomatosis affect not only the skin but also the internal organs with which these cases did not have much in common. Angiomatosis indicates a disturbance of development or perhaps a true neoplasm so I would

²⁷ Gans, Oscar. Ueber perzische Hautveränderungen bei Erythraemie. Virchow's Arch. f. path. Anat. 263: 515, 1927.
²⁸ Clough, Paul W. Diseases of the Blood. New York: Harper & Brothers, 1929. p. 174.

suggest that the author insert the term generalized telangiectasis merely for the purpose of cataloguing the cases. These cases, which I had occasion to study some years ago, bring up interesting questions in dermatology. With the exception of infectious infestations and neoplasms, dermatoses are confined almost entirely to the human race, so it is impossible to do much animal experimentation in the field of dermatology. Man differs from animals in his central nervous system and there is evidence that many dermatoses other than telangiectasis are definitely influenced by the nervous system. I should like to mention one case that was treated in Professor Bloch's clinic and which I reported some years ago, the agent used being thorium X. This gives a very prompt thrombosis of the external vessels and a good result. Some years ago I corresponded with the Welsbach people, who had thorium at their disposal, but they did not feel able to make thorium X available. Dr Sulzberger tells me that an effort is now being made to have thorium X available in this country.

DR SAMUEL M. PECK, New York. In the group of telangiectases which Dr Madden discussed, one of the most important and the most difficult therapeutically is the hereditary telangiectasis of Osler. These patients often have severe hemorrhages especially from the nose and mouth with marked secondary anemias. For three years I have been treating bleeding symptoms of various types with snake venom. Among this group there were a number of cases of Osler's disease. If these patients are injected over a long enough period the bleeding symptoms are definitely controlled. After about six weeks with two injections weekly the hemoglobin rose markedly and the bleeding symptoms either disappeared or were markedly diminished in amount and in frequency. Much to my surprise in two cases the telangiectasis disappeared entirely or almost entirely from the mucous membranes. In the group of functional nasal bleedings the preparation was almost specific. Only a few injections were needed to stop the bleeding and in most of the cases there was no recurrence after the treatment was stopped. This was in contradistinction to the Osler cases in which a maintenance dose had to be determined. Very good therapeutic results were also obtained by the use of snake venom in purpuras of various sorts as well as in uterine bleeding.

DR JAMES HERBERT MITCHELL, Chicago. I have seen three instances of telangiectasia in pregnancy. The first patient was 25 and it was her first pregnancy. When told that there would probably be complete clearing after delivery, she did not wish to submit to any further investigative work. The second patient is to be delivered in July and the third is now six and a half months pregnant. The first case I saw in the literature was that of Gougerot, he mentions the cases of Brocq and one other. These I have not looked up. The lesions were not generalized but were limited to exposed areas of the skin. A startling finding in my third patient, a woman aged 31, was that she was exposed to very bright sunlight ten days before observation. She was wearing sleeves that reached to the elbow and the telangiectasia appears there and over the face, the nucha and the upper portion of the chest. This third patient, who has promised to do anything in the way of investigative work, I wish, tells me that her father had no telangiectasia. She had a German mother with a very fair skin. I happen to know the parents of both of the first two patients and there is no telangiectasia. These cases all clear up following delivery and there is no tendency toward bleeding so far as I know.

DR FRED D. WEIDMAN, Philadelphia. I wish to suggest that there are "formes frustes" in this condition and that sometimes they may point in a rather roundabout way to serious internal medical states. A young woman told me some time ago that she had had eight miscarriages and yet was extremely eager to have children. I noticed a few telangiectases on the face and it developed that when she becomes heated or excited marked rosacea occurs and an ordinarily inconspicuous angiectasis of the face becomes marked. Her mother also has rosacea. I have gone over her carefully and could find no evidence of generalized telangiectasia, nasal or otherwise. However, she also had a rather pasty anemic color. Blood studies have not been completed but I feel that she may have a certain degree of fragility of the red blood cells. She has achlorhydria and

gastro enterologists tell me that the present trend of thought is that all the primary erythrocytic anemias probably originate in disturbance in gastric function, notably with lack of hydrochloric acid. In short, this young woman has a number of vague maladies, some of which can be associated with those mentioned this afternoon. One of Dr Madden's patients had myelogenous leukemia. Of course, it is a long step from myelogenous leukemia to primary pernicious anemia, but in any event there is a message to internists as well as to dermatologists that in connection with anemias one of the features to receive study is lesions on the skin as well as on the mucous membrane and not alone as to purpura but also other more or less allied disturbances of the capillaries.

DR JOHN F. MADDEN, St Paul. Answering Dr Ebert's question, no biopsies were made in the cases with pregnancy. Dr Mitchell said that the patient he has under observation is willing to have a certain amount of investigative work undertaken and I think he will undoubtedly answer that question in the future. As to Dr Becker's suggestion, I think too that telangiectasis is generally considered as the dilatation of existing blood vessels, and angiomas as the formation of new blood vessels. In the cases reported both of these conditions existed, therefore I am including both terms in the title of my paper. Dr Peck's use of snake venom is interesting. Most observers believed that the use of horse serum, snake venom and the like in hereditary hemorrhagic telangiectasia presupposes some abnormality in the blood that no one has been able to find. Hence they have found such medication of no value. However, I shall certainly try Dr Peck's therapy.

TRANSFERENCE OF INGUINAL GLANDS IN HUMAN SYPHILIS

C. J. LUNSFORD, MD

OAKLAND, CALIF.

AND

P. W. DAY, MD

REPRESENTA, CALIF.

During the last decade a great deal of work has been done in intratesticular inoculation of rabbits with material from human lymph nodes infected with *Spirochaeta pallida*. Brown and Pearce¹ and Ebersson, among others in their work with experimental animals established the fact that *Spirochaeta pallida* has a predilection for lymphoid tissue and rapidly disseminates therein. Engman and Ebersson² studied the problem of infectivity in fifteen cases of latent syphilis and demonstrated the presence of *Spirochaeta pallida* in 20 per cent of the inguinal glands transplanted. Chesney and Kemp,⁴ in an attempt to utilize the method as a biologic criterion of cure in cases of three thoroughly treated patients with early syphilis obtained completely negative results in all. The authors comment that negative results are interesting but do not solve the curability of syphilis. They further suggest that such "negative results must be controlled by a study of the infectiousness of the nodes of a series of untreated patients whose syphilis dates back at least several years." Greenbaum's⁵ studies, published in

The information contained in this paper is based on studies of the inmates of Folsom Prison.

Read before the Section on Dermatology and Syphilology at the Eighty-Fourth Annual Session of the American Medical Association, Milwaukee, June 15, 1933.

May, 1930, indicated that transference of inguinal glands into the testes of rabbits could not be utilized as a criterion of cure in chronic syphilis, because transference of the glands of 60 per cent of untreated patients into rabbits gave a negative result. All of these studies have a distinct interest in relation to the study we have conducted.

Among the inmates at Folsom Prison are many persons infected with syphilis. Such a circumstance offered a ready means for the use of human material in an attempt to verify some of the modern teaching relating to the proper management of cases of syphilis.

The studies on which this paper is based were begun in January, 1930, and have continued to date as new material became available. We studied 100 cases, in all there was a 4 plus Wassermann reaction. With the exception of the 8 patients with primary syphilis, all were free from signs or symptoms of syphilis.

For purposes of analysis, the cases are classified into the following groups (table 1).

- 1 Patients with primary syphilis with a positive result of dark field examination
- 2 Patients with late or chronic syphilis
 - (a) Those under active treatment at the time of operation
 - (b) Those with a record of treatment before operation
 - (c) Those without previous treatment (latent syphilis)
 - (d) Those untreated with a 4 plus Wassermann reaction of the spinal fluid and a paretic curve
 - (e) Those whose glands produced a positive result in rabbits, who were treated and later operated on

TECHNIC

The technic of transferring the inguinal gland tissue from the syphilitic patients to the rabbits was as follows:

Procaine hydrochloride was injected around the most prominent lymph node without infiltrating the glandular tissue. The node was removed and immediately emulsified in approximately 0.5 cc of physiologic solution of sodium chloride. A drop of this emulsified tissue was subjected to dark-field examination, and about 0.5 cc was injected into the testes of a healthy full grown rabbit. The injection was always carried out within ten minutes after the gland was excised, and a notation was entered of the testes into which the injection was made.

Each inoculated rabbit was confined separately in a well ventilated cage from six to ten weeks before autopsy, at which time the testes were removed and treated in a similar manner to the nodes removed from the patients. If they were found to be negative on dark-field examination they were reinoculated into a second healthy rabbit.

The second group of rabbits was in turn autopsied after an incubation period of from six to ten weeks. Often gravish nodules and marked edema of the testes could be seen grossly at autopsy, and the lymph glands in the inguinal region were seen to be enlarged and injected. Those that showed live *Spirochaeta pallida* on dark-field examination were recorded for purposes of analysis.

RESULTS

1 *Primary Syphilis* (table 1).—Study was made of eight cases of primary syphilis. All showed a positive result on dark-field examination of material from the chancre as well as from the inguinal gland at the time of operation. Of the animals given injections one died in a few days and autopsy was not performed. When the remaining seven animals were killed the testes showed active virile *Spirochaeta pallida*. The percentage of positives in live rabbits was 100. Greenbaum's studies had proved beyond doubt that primary syphilis could be transmitted to rabbits in 100 per cent

of cases. Our study of this particular stage of syphilis was undertaken in order to prove the efficiency of our technic.

TABLE 1—Cases of Primary Syphilis

Classification	Number of Cases	Wassermann Reaction of Blood	Treatment	Results in Rabbits	
				Positive	Negative
Primary	8	Negative	None	7	
Late syphilis	19	4+	Under treatment		19
Late syphilis	1	4+	Previous treatment but none for two years	12, or 31.5%	26
Late syphilis	29	4+	No previous treatment	11, or 35%	13
Dementia paralytica 4 plus Wassermann reaction of spinal, fluid and paretic curve	6	4+	No previous treatment		6
Total	100				

2 *Cases of Late or Chronic Syphilis*.—Patients Under Treatment at the Time of Operation (table 2). We were able to obtain the cooperation of nineteen patients under active treatment. At the time of operation each was receiving weekly injections of 0.6 Gm of neoarsphenamine. Fourteen of these had shown a reversal of the Wassermann reactions of the blood.

TABLE 2—Chronic Cases. Inguinal Glands Transferred to Rabbits During Period of Treatment

Number	Wassermann Reaction of Blood	Treatment	Spinal Fluid	Rabbits
19 receiving 0.6 Gm of neoarsphenamine	4+	118 2.0 injections of neoarsphenamine Wassermann fast 14 70 91 injections of mercury	6 positive 11 negative 2 not done	All negative

at previous times, and were regarded as being Wassermann-fast. Six of these Wassermann-fast cases showed a positive reaction of the spinal fluid. The patients had received from 118 to 230 injections of neoarsphenamine and from 70 to 91 injections of mercury. Eleven of the remaining 13 patients had a negative reaction of the spinal fluid. In 2 cases examinations of the spinal fluid

TABLE 3—Cases of Late or Chronic Syphilis

Previously treated patients 33 (none within 2 years)	Positive 12 or 31.5%	Began treatment	
		3 primary	3 early secondary
		6 late secondary	
		6 had had intensive treatment	52 injections of neoarsphenamine average
		1 had had as many as 300 injections of anti-syphilitic therapy before 1923	46 injections of mercury average
		Negative 26	

had never been made. The patients who were not regarded as Wassermann-fast had been undertreated. They had received an average of 16 injections of neoarsphenamine and 13 of mercury or bismuth. In no case were we able to obtain a positive result in rabbits.

Patients with a Record of Treatment Before Operation (table 3). Rabbits were inoculated with the glands from thirty-eight patients with syphilis who

cases of chronic syphilis in which the patients were under active treatment. In no case were we able to obtain a positive result in rabbits. From the standpoint of public health, the study offers biologic support to the idea that at least during the time patients are under active treatment the threshold of their infectivity has been reduced to a level where it would appear to be difficult to transmit the infection to other persons.

TABLE 5—Patients Under Active Treatment

	Cases	Rabbits
Previously studied	19	Negative
Cases formerly showing positive results in rabbits	5 (treated for — 2 years)	Negative
Total	24	

SUMMARY

The results obtained from the intratesticular inoculation of rabbits with human material from 100 cases of syphilis with a 4 plus Wassermann reaction are as follows:

1 In eight cases of primary syphilis 100 per cent of the gland transplants caused positive results in live rabbits.

2 The glands of twenty-four patients with chronic syphilis who were under treatment caused negative results in rabbits.

3 In 38 per cent of twenty-nine cases of untreated latent syphilis, the results in rabbits were positive.

4 For six patients with untreated dementia paralytica inoculations into rabbits gave negative results.

5 The glands of twelve of thirty-eight patients previously treated for chronic syphilis gave positive results. Six of the twelve patients had received intensive treatment, averaging fifty-two injections of neosphenamine and forty-six of mercury.

6 Three patients with acute syphilis who were adequately treated according to present standards showed live *Spirochaeta pallida* in their inguinal glands after a lapse from treatment extending from three to five years. The conditions were diagnosed early, the patients were treated intensively and later were pronounced cured on the evidence of completely negative clinical and serologic findings.

CONCLUSIONS

1 The diagnosis of primary syphilis by means of gland puncture can be made in 100 per cent of cases.

2 It is probable that patients with late syphilis are not a menace to others while undergoing active treatment.

3 A comparison of the 31.5 per cent positive results obtained in previously treated patients with syphilis with the 38 per cent positive results obtained in untreated patients indicates that, from the standpoint of the biologic cure of the patient, inadequate treatment is very little better than none at all.

4 According to our findings *Spirochaeta pallida* is not present in the cerebrospinal fluid.

5 There is a necessity for frequent reexamination of patients with syphilis even though it appears that they have been adequately treated according to modern standards.

6 The clinical and serologic tests used as criteria of cure in syphilis are inaccurate and must be revised with increasing knowledge of the disease.

ABSTRACT OF DISCUSSION

DR M F ENGMAN, JR, St Louis. It is very difficult to discuss this type of work. In the first place not much is known about syphilis. Clinical experience and laboratory evidence result in some impressions, which should not become fixed. The authors take out one small bit of tissue from an entire body and this, of course, is the main objection to drawing conclusions from this type of work. They find in many cases negative rabbit inoculations. They find no evidence of spirochetes, that being the only basis on which they can declare that no spirochetes are there. However, the value of it lies in the positive evidence. The fact that they found no spirochetes in this bit of tissue does not mean that there are none in the body or, as Warthin pointed out, a large percentage of patients who have had syphilis in active form still have it although it is quiescent. I think that the authors have been conservative in their conclusions. They have 100 cases. They get different results from cases of different type and that requires study. Probably such work as theirs can be better digested after a few years, when it is hoped that more information will be available. The fundamentals of the disease are really not known. The authors report 100 per cent of cases of primary syphilis. It would be interesting to have some cases presenting no lesions on the genitalia or in the glands. It would be expected that they would have 100 per cent in those for at least the greater part of the body is invaded by the organism at some time in the course of the disease, and since the glands are prone to retain the spirochetes they should find them in 100 per cent. The authors show, and Dr Greenbaum and my father showed some years ago, that, although the disease is still present in a latent form there are no symptoms. In latent syphilis one is dealing with a different problem. Is the spirochete present? It is. Where is it present? No one knows. The authors found them in a certain percentage of the glands in their patients. It is known that there is an immunity and that Chesley and others have produced immunity in rabbits and then injected spirochetes into the skin and yet produced no allergy. In the same way the authors find spirochetes in the glands by biologic methods and still there is no reaction.

DR J GARDNER HOPKINS, New York. I rise to express my admiration for an excellent and informative piece of work. I doubt very much whether any one can obtain 100 per cent takes in passing strains from man to the rabbit. It is very different in passing from rabbit to rabbit. I doubt, too, whether the authors' percentage in chance cases can be taken as an index of what would be expected in cases presenting positive glands for the dose of spirochetes is important. If one finds in 30 per cent of gland cases a positive rabbit take one cannot assume that the remaining 70 per cent are negative. I think a great many would be positive. The positive results would suggest that with intensive methods and using a larger amount of tissue one might get a higher percentage of takes.

DR P W DAY, Represa, Calif. Dr Lunsford and I have not had any patients with treated syphilis serologically negative who have had gland tissue transferred to rabbits. Such a series of cases would add much to the value of our work if any were found positive. It might be well to mention something of the technique we used in transferring this tissue from the human being to the rabbit. The most prominent inguinal gland present was removed under procaine infiltration, without injection of the gland. It was emulsified with saline solution and immediately subjected to dark field examination, and within ten minutes 0.5 cc. was injected into the testicles of rabbits. These rabbits were allowed to live for from six to ten weeks and were then killed and examined. Then the testicular tissue was subjected to dark field examination. If any enlarged glands developed these also were examined. If negative, a second injection into rabbit was made and this group allowed to go through the same incubation period. The cases of primary syphilis were examined to check our technique and all showed *Spirochaeta pallida*. All late cases of syphilis were institutional cases of prisoners who could be kept under close observation over a long period. We appreciate their willingness to cooperate in this work.

TWO IMPORTANT BIOLOGIC FACTORS
IN FERTILITY AND STERILITY

- (a) IS THERE A "SAFE PERIOD"?
(b) ANOVULATORY MENSTRUATION AS A
POSSIBLE CAUSE OF STERILITY

EMIL NOVAK, M.D.
BALTIMORE

Whether right or wrong, the birth control movement has moved forward from the shadows of guarded discussion into the limelight of medical social and even religious publicity. Some of our profession are enthusiastic supporters of the movement, some are apathetic, some opposed, and many, though recognizing the justifiability of contraception in many instances, deplore the fact that a problem so individual should have assumed the proportions of a mass propaganda. With many patients the undesirability of further pregnancies is inextricably complicated by the factor of religion. With such patients continence alone has heretofore appeared to be the price demanded for safety from the possibility of pregnancy, and no one could be so religiously blind as to believe that this price has always been paid.

The first purpose of this paper is to evaluate briefly, with a minimum of citation from the now voluminous literature, the status of a biologic means of contraception to which, I believe, no church finds objection. Many medical men have become familiar with the general principles of this question, as have some of the laity, through a number of lay publications on the subject. However, there is still a rather heavy haze surrounding the subject, and still much lack of unanimity as to the practical value of "biologic contraception," so that it would seem worth while to evaluate its present status.

There are a number of fundamental considerations on which the discussion of this question rests. The egg is extruded from the ovary practically always at some time varying from the eighth or ninth to the eighteenth or twentieth day of the usual twenty-eight day cycle exhibited by most women. Most often ovulation occurs at about the twelfth to the fourteenth day. The life of the ovum after its extrusion from the follicle is very short, probably not more than a day or so, and, according to some, only a few hours. This is contrary to the older view, now definitely disproved, that the life span of the ovum is about two weeks. From the standpoint of the female alone, therefore, the time at which ovulation occurs is for practical purposes the only time at which fertilization can occur. The problem, therefore, is to determine at what time ovulation occurs. Were it possible to do this in the individual patient, the question would be greatly simplified.

From the standpoint of the male, the chief factor to be considered is as to how long the spermatozoa retain their potency after injection into the genital canal. Here again views have changed. Whereas it was formerly thought that in man, as in some lower animals, spermatozoa may retain their potency for many days, the evidence now seems quite clear that, while they may retain their motility longer, they lose their capacity to fertilize the ovum in two (Knaus) or three (Ogino) days. Combining the male and female factors, therefore, it would seem that the time at which fertilization can occur is the ovulation phase plus about three days

to allow for the possibility of survival of previously injected spermatozoa, plus perhaps a day or so to allow for the possibility of survival of the ovum for that period after ovulation.

These, in bare outline, are the principles governing the various precepts of biologic birth control which are now being so widely discussed. How are they applied, and what is their value?

The first to suggest the possibility of a "safe period" in the cycle was Capellman¹ in 1883, although his recommendations were quite different from those now given, and according to newer knowledge, very incorrect. Interest in the subject was apparently abandoned until the publication by a number of German authors (Siegel² and others) of the results of studies in a large number of German women whose husbands returned home for short furloughs during the World War. These studies were purely clinical, and the results cannot, for obvious reasons, such as lack of precision as to the dates of menstruation and coitus and the presupposition of chastity in all these patients, be considered as above scientific criticism. I shall not review these results in this short paper, the purpose of which is rather to discuss briefly the more important observations that have been made more recently by a group of investigators who have attempted to correlate the physiologic and clinical points of view in the study of this question.

In 1924, and in several other papers since then, Ogino³ has presented evidence to indicate that the possibility of fertilization is limited to a definite phase of the cycle. In the woman with a twenty-eight day cycle, ovulation occurs from twelve to sixteen days before the next menstrual period, and the conception period is limited to the eight days between the twelfth and nineteenth days before the next period. The latter, therefore, is taken as the point of departure, in the view that the postovulatory or corpus luteum phase of the cycle is the one of fixed duration, an assumption that does not agree with the results obtained by Hartman in the far more scientifically controllable study of the monkey cycle. Ogino admits the possibility of fertilization in the five day period preceding the span indicated but considers this very remote.

The difficulty that it once suggests itself is as to the application of this rule in women with cycles of other than the common four-weekly type. It is a well known fact that women vary much in this respect, and that in the individual woman there may be frequent and perhaps wide variations in the length of the cycles. Ogino stresses the importance of careful chronological study of many menstrual cycles whenever possible. The beginning of the eight day "conception period" he puts at ten days plus or minus the difference in days between twenty-eight and the minimal length of the cycle. The end of the dangerous phase he places at seventeen days plus or minus the difference between twenty-eight and the maximal length of the cycle. To put it another way, the woman determines her "safe period" on the basis of her shortest cycle, and also of her longest cycle. The overlapping "safe days" constitute her "safe period." As already emphasized, the reckoning is from the expected period back, the nondangerous span being that embraced between the twelfth and nineteenth days, inclusive.

This paper contains references to previous publications by the author.

Knaus,⁴ another indefatigable worker in this field, has contributed what is apparently the only test method for ovulation in the human being, through a study of the sensibility of the uterine musculature to the action of posterior pituitary extract under the influence of the follicle and corpus luteum hormones. The latter render the uterus refractory to the action of the pituitary principle. By the study of the time of onset of this unresponsiveness he arrives at conclusions not unlike those of Knaus, stating that fertilization always occurs in the period between the eleventh and seventeenth days of the cycles, if the latter is of the usual four-weekly type. Both writers have made clinical reports of results by this method which appear to bear out their contentions.

As opposed to these, Grosser,⁵ Bolaffio,⁶ Niedermeyer,⁷ and others deny the infallibility of the Ogino-Knaus doctrine, and with what appear to be weighty reasons. Grosser, for example, urges that the careful study of the age of twenty-four early embryos indicates that in ten of these conception occurred between the second and tenth days of the cycle, in ten at from the eighteenth to the twenty-fourth, and in only four in the period emphasized by Knaus as the conception phase, i. e., the eleventh to seventeenth days. Grosser is a strong believer in the view that coitus in itself may be an important determiner of ovulation, as it is in the case of such animals as the rabbit. There is no proof of this occurrence in the human being, but its possibility cannot be denied, even if one accepts the usual doctrine that spontaneous ovulation is the rule and that it occurs at fairly stated periods. Bolaffio and Niedermeyer likewise, and on essentially the same grounds, object to the general applicability of the Ogino-Knaus doctrines.

The problem has been merely outlined in these paragraphs, and only a fraction of the literature touched on. What may the present status of the question be considered to be? In spite of the possible, though not proved, occurrence of coital ovulation, there would seem to be no doubt on mere a priori grounds that the optimal conception period is in the span that embraces most ovulations, i. e., from the eighth or tenth to the eighteenth or twentieth day of the cycle, with the maximum at about the twelfth to the fourteenth day. This conforms to the results noted by Hartman⁸ in his mating experiments with monkeys. The foregoing statement would apply to the most common cycle, varying from twenty-six to thirty days in length, while for irregular cycles some such adjustment of calculations as that suggested by Ogino is probably a serviceable one.

This, however, is quite different from saying that conception is absolutely impossible at other times as has been claimed. Too little is known as yet about several of the possible factors in fertilization to justify such a claim. As already stated the possibility of coital ovulation must be borne in mind, even though its occurrence in the human being has not been demonstrated. The survival time of the ovum is generally accepted as short but the evidence for the period of survival of the spermatozoon is not yet quite as clear as might be hoped though it is probably not as long as formerly thought. Again there is still considerable uncertainty in women with irregular cycles, as to the part played in

this irregularity by the preovulatory and the post-ovulatory phases of the cycle.

To sum up, in women with cycles approximating the four weekly type, there is every reason to believe that the immediately postmenstrual period (up to the eighth day of the cycle) and even more the immediately premenstrual period (after the twentieth day) are almost entirely, though perhaps not absolutely, "safe periods" for those anxious to avoid conception. In women with irregular cycles the problem is more difficult and less certain, though probably a great measure of protection may be given by following the suggestions of Ogino, as described.

For those who, because of religious or other reasons, are not willing to resort to other forms of contraception, the Ogino-Knaus method is a great boon and is certainly the one that should be recommended by the physician. To avoid embarrassment, however, especially in women with irregular cycles, it would seem wise to emphasize the fact that not a sufficient time has elapsed as yet to demonstrate clearly how great or how slight a degree of fallibility pertains to this method and how this fallibility compares to the recognized fallibility of practically all other methods of contraception.

From what has been said, it is obvious that in the opposite case of women very desirous of having children the optimal time for coitus is that extending from the tenth to the eighteenth day of the cycle, and especially from the twelfth to the fourteenth day. This advice I have for many years considered an important part of the management of cases of sterility.

ANOVLATORY MENSTRUATION AS A CAUSE OF STERILITY

A problem antithetical to the one just discussed is that of sterility. No type of patient elicits the sympathy and cooperation of the gynecologist so fully as does the woman with high maternal ideals who is willing to make any sacrifice for the possibility of bearing a child. Many possible factors must be considered in both the partners, and in most instances a careful study will reveal one or more logical causes for the sterility. In many instances a rational plan of treatment will thus be indicated, with some measure of optimism as to results. In other cases, unfortunately, such studies reveal causative factors that must be considered hopeless.

There is, however, a not inconsiderable group of cases in which the most thorough studies of both partners—general physical examination, examination of the pelvic organs, basal metabolism studies, tubal insufflation tests, hormone tests of various sorts—all reveal no demonstrable abnormality, and yet pregnancy does not occur. In instances of this sort there is always the temptation to explain the sterility as due to an incompatibility of the germ cells of the couple, and at times this appears to be confirmed by the ready occurrence of pregnancy with a new partner. Such an explanation, however, if it can be called an explanation, can apply to only a small proportion of cases and most often such observations are open to scientific objection on one ground or another. They would obviously be of no significance unless both partners in a sterile union later demonstrated their fertility with new mates.

It is in this small group of otherwise unexplainable cases that I believe that the sterility may at times be due to the fact that the woman, who perhaps is menstruating normally and regularly and who is presumably normal in every other way, is not giving off eggs

8 Hartman C. C. Am J Obst & Gynec. 26: 600 (Oct.) 1933

I have in several previous papers⁹ urged that anovulatory menstruation, so common in monkeys, is not nearly so rare in women as was once believed. That it occurs in some women is beyond dispute. Functional menorrhagia, at times not very excessive, is characteristically associated with an anovulatory mechanism and undoubtedly it occurs in some cases in which the menstrual flow is within normal limits. I believe the same mechanism occurs in a certain proportion of women for a time after puberty and for a time before the actual menopause though it may occur at any age in the reproductive epoch.

It need scarcely be said that the anovulatory type of cycle is the unusual one in the human female and that ovulation and corpus luteum formation are the rule. It is idle in the present state of knowledge to speculate about the numerical frequency of anovulatory menstruation. It probably occurs in only a small proportion of menstruating women but the proportion in the cases of unexplainable sterility may prove to be not inconsiderable.

Is there any way of determining whether or not a sterile woman is ovulating? This question can be answered in the affirmative. The most direct and logical method is through study of the endometrium just before an expected menstrual flow assuming that the periods recur regularly. If ovulation has occurred the endometrium will show the characteristic secretory changes evoked by the corpus luteum hormone (progesterone). If, on the other hand, there is a complete absence of secretory changes it may be assumed that there is no corpus luteum, i. e. that ovulation has not occurred.

The tissue for examination can often though not always be obtained without anesthesia by using a very small curet. It is not necessary to perform a complete curettage. Even if dilation of the canal under light anesthesia is necessary in order to secure the tissue the value of the information gained makes this well worth while. The suction method suggested by Klingler and Burch¹⁰ has been employed with success though I prefer the curet as it gives larger pieces of tissue.

I have employed the method thus far in only a small series of cases for the patients in whom it is indicated are not very numerous. Even this small experience however has demonstrated that some of the patients have been sterile presumably for the simple reason that they are not giving off eggs. Even if this in itself were not an obvious factor the absence of the corpus luteum would prevent pregnancy for on the corpus luteum secretion depends the preparatory preparation of the endometrium so necessary for implantation of the egg.

Can anything be done in a therapeutic way in cases of sterility due to failure of ovulation? In some of the lower animals such as the rabbit ovulation can be induced by the injection of pregnant urine a principle on which the well known Friedman test is based. The injection of the piolan-containing principles obtained from the urine of pregnant women would therefore seem to be logical although how great are the species differences in hormone reactions and how much less the human ovary reacts to the principles contained in the pregnant woman's urine than do the ovaries of some of the lower species are already well known. And yet

this is, so far as I see, the only plan of organotherapy that seems open at the present time.

Since the ovaries of these patients probably contain follicles which reach maturity, but which, instead of rupturing, undergo a gradual desiccation, the temptation presents itself in such cases to attempt rupture of the follicles by gentle manual pressure over the ovaries. Unfortunately it is not usually possible to determine by bimanual palpation which ovary is the seat of an impending ovulation as Hartman has shown can be done by rectal palpation in the monkey. Furthermore, there is always the theoretical chance of causing troublesome intraperitoneal bleeding though I think that this would be relatively slight. While, therefore, I have not employed this method myself as yet, I do feel that in the properly selected case gentle pressure over both ovaries at the proper time in the cycle would be justified if the patient can be properly watched for a time after the procedure. However, with the rapid progress which is being made in reproductive endocrinology it would seem certain that before long some safer endocrinotherapeutic means of inducing ovulation in these cases will be evolved.

Clinical Notes, Suggestions and New Instruments

SPONGE HOLDING FORCEPS WITH BUILT IN BOTTLE STOPPER

PAUL R. FARRINGTON, M.D., BOULDER, COLO.

This forceps is designed to be kept constantly in a bottle of volatile antiseptic solution but to be ready for instant use. Incorporating a stopper in the handle prevents evaporation of the solution.

An ordinary ring sponge holding forceps is selected and thoroughly cleaned. A bottle is then chosen which is of sufficient size to allow the forceps to rest in it as far as the ratchet. Cotton is firmly packed in the neck of the bottle about the forceps to prevent the wax from running into the bottle. A thin piece of sheet brass is trimmed to fit and inserted between the handles of the forceps in the neck of the bottle as a partition. Melted dental wax is then poured into the neck of the bottle and molded to make a stopper for the bottle surrounding the handles. The neck of the bottle is then carefully warmed in the Bunsen flame and the wax stopper and forceps are removed together. The projecting upper part of the brass partition is then carefully warmed and the forceps opened dividing the stopper into halves one of which surrounds each of the handles. A sprue wire is attached to each half of the wax and the opened forceps is embedded in plaster of paris, dried in an oven for eight hours at 350 F and the wax boiled out. A casting is then made with bearing metal after which the plaster is carefully chipped away and the work polished.

This makes a snug fitting stopper for the bottle, which prevents evaporation and does not interfere at all with the operation of the forceps.

ANOSCOPE

HARRY E. BACON, M.D. PHILADELPHIA

Many anorectal disorders are present immediately above and below the anorectal or pectinate line, yet, because of inadequate illumination and the use of the ordinary conical speculums thorough examination is often difficult and most unsatisfactory. But good illumination and inspection of the diseased area are essential in making a correct diagnosis. The treatment of many lesions at this site are office or clinic procedures, but not infrequently a nurse or an assistant is not at hand which necessitates removal of the patient to the hospital. For this reason a self-retaining device is a helpful adjunct. With the patient in the left lateral, or Sims position this procedure may be accomplished by means of the illuminated anoscope shown in the illustration. The instrument is self retaining and may be easily introduced after the anus has been smeared with a water-soluble lubricant. The light, located

Anoscope

in the head of the detachable handle is directed diagonally to the opposite side where the scope is slit. On rotation of the instrument the anal canal and lower rectum are visualized permitting digital and instrumental examination. Aside from diagnosis, topical applications are more easily accomplished and hyperplastic papillae, inflamed crypts, and small or moderate-sized thrombic hemorrhoids may be readily excised following the injection of a few minims of a local anesthetic into the base of the area to be treated.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
H. A. CARTER, Secretary

HEMP MASSAGER NOT ACCEPTABLE

The Hemp Massager is manufactured by the Conley Company, Inc., Rochester, Minn. Briefly, this device consists of two rubber balls mounted on spindles at right angles to each other. At right angles to the plane of these spindles the handle is attached. Three sets of rubber balls are supplied with a complete outfit and are interchangeable. As this device is pulled along over the body the rubber balls pinch the skin and by friction lift it and underlying superficial tissues above the contour of the body or limbs. The angle at which the handle is raised with respect to the body surface determines the firmness, the vigor of the massaging action.

One unit was investigated by the Council. The Council declared that it did exactly what, in practicing good massage a masseur tries to avoid: it pinches the superficial tissues instead of picking up and kneading deep tissues as well as the superficial.

Even if the massager faithfully duplicated hand massage there are certain statements recorded in the booklet *How to Use Your Hemp Massager* which the Council regarded as exaggerated. For example on page two under *The Only Device that Massages Like Human Hands*, it reads: "The Hemp Massager used as directed in this booklet brings to you in your own room the benefits of a trained masseur." This statement is interpreted by the Council as misleading.

On page four under *Reducing*, "Massage assists in reducing that fatty tissue which accumulates due to lack of proper exercise. Sometimes excessive fat is the result of an organic disorder and in such a case a physician should be consulted as it may not be advisable to attempt to reduce this form of fatty tissue by massage alone." Generally it is advisable to use the small sphericals for reducing. On hips or

abdomen, stroke in all directions, finishing up with a few strokes toward the heart, using the large sphericals. Do not massage any one part of the body more than five minutes. Be consistent and massage every day." The firm has not submitted evidence to substantiate the foregoing statement.

On page eight, under "Massage for the Face," "Massage stimulates circulation of the blood and tends to improve the complexion. At the same time, it firms the muscles, removes superfluous flesh and smooths out wrinkles. Consistent massage is one of the best ways to remove double chins." This statement is considered misleading.

On page nine, under "Scalp Massage," "One of the most effective ways of keeping hair strong and healthy is to keep the scalp clean and free from scale by massage. Massage will often check falling hair." If this outfit is employed the firm has not submitted critical evidence to substantiate the foregoing statement.

On page ten, under "Headaches," "Properly applied massage will usually relieve the discomfort of simple headaches."

Do this along the heavy cords down the back of the neck, as well as along the hollow in the center. Stroke gently and slowly, always down and away from the head. Continue the massage for about two minutes, and repeat after an hour or so until relieved. The statement concerning headaches is regarded as misleading.

On page eleven under "Constipation," "This is a cause of much discomfort, headaches, loss of pep and energy. It may also lead to more serious ailments. Proper massage by stimulating and strengthening the muscles of the abdomen and along the large intestine, is frequently effective in relieving constipation in a natural safe manner."

Starting at the lower right of the abdomen, stroke along the course of the large intestine, up the right side, across above the navel and down the left side. Lie on your back, knees up with abdominal muscles relaxed. Massage for five minutes. Also massage the small of the back night and morning." The Council does not agree with the contents of this statement. Critical evidence is needed to substantiate the claims.

In fairness to the manufacturer there is recorded on the back of the cover, "Caution: Use very lightly if at all over varicose veins. Do not use in cases of ulcers, fevers, bleeding, tuberculosis, infections, broken bones, diabetes or on the breasts unless by the consent of a physician. We recommend that before using the massager for any specific bodily ailment, you first get competent medical advice."

On a folder entitled *Would You Like a Trim Healthy Body?*, the following is recorded: "Enjoy the Grace of a New Slender Figure. The benefits of a professional masseur at your convenience. Massage, to be effective must be properly and consistently administered. But few can afford the services of a professional masseur over a period of weeks. Now, however, with the aid of the Hemp Body-Massager you can give yourself a thorough complete massage in 15 minutes in the privacy of your own home."

In another place, one reads: "Massage Relieves Many Bodily Ailments. Valuable for Athletes and Dancers. Massage properly administered, stimulates circulation, thus helping the blood in its natural process of feeding the muscles and tissues of the body, and carrying away impurities. Athletes and dancers are well acquainted with the effectiveness of massage in relieving stiff sore muscles, charley-horse, etc. Massage is frequently effective in relieving the discomfort of headache, rheumatism, nervousness, constipation and other troubles. However, if you are not well, we recommend that you consult your physician. It will benefit you, he will advise you how it should be applied to produce the desired results. Do not attempt treatment for specialized ailments without first getting competent medical advice."

Promotional advertising matter of this kind containing the aforementioned objectionable phrases or statements is bound to be misleading and in effect constitutes an appeal to the public for arguments that are unscientific and may harmfully enhance a feeling of false security on the part of the public.

The Council declared that if hand massage is given by a technician or masseur and used properly, it may stimulate the circulation, speed up metabolism, relieve stiff and painful joints and sore muscles. The Council objected to the claims made

for the relief of headache, nervousness and constipation. In reality, these conditions might be caused by some impaired function other than that for which massage is justly indicated. The aforementioned statement taken from the advertising matter for the Hemp Messenger the Council regards as objectionable, because satisfactory evidence is not in its possession to substantiate the efficacy of massage with this unit in the conditions mentioned. Owing to the foregoing inconsistencies with the Official Rules, the Council declares the Hemp Messenger ineligible for inclusion in the list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS IFFCH, Secretary

METYCAINE—Benzoyl γ (2-methylpiperidino)-propanol hydrochloride— γ -(2-methylpiperidino) propylbenzoate hydrochloride— $C_6H_5COO(CH_2)_3NC_6H_5 \cdot HCl$ —The base of metycaïne differs from the base of procaine hydrochloride in having the basic nitrogen in a methylpiperidino ring instead of the dimethylamine γ propanol group in place of the ethanol group and in not having an amino group attached to the benzene ring. In addition, it possesses an asymmetrical carbon atom and is optically inactive. Metycaïne is therefore a racemic mixture of the hydrochlorides.

Actions and Uses—Metycaïne is a local anesthetic which produces prompt anesthesia either by subcutaneous injection or topical application to mucous membranes and similar surfaces. Pharmacologic studies on animals indicate that the toxicity of metycaïne following subcutaneous injection is lower than that of cocaine and comparable to that of procaine, intravenously it was found to be approximately three times as toxic as procaine.

Dosage—For application to the eye metycaïne is used in 2 per cent solutions, for nose and throat 2 to 10 per cent solutions are used, 1 to 4 per cent solutions have been used for urethral anesthesia, for infiltrative anesthesia in small areas solutions of 0.5 to 1 per cent are generally used.

Manufactured by Eli Lilly & Co. Indianapolis, Ind. U. S. patent 1,784,903 (Dec. 16, 1930; expires 1947). No U. S. trademark.

Ampoules Metycaïne 1% 1 cc. Each cubic centimeter contains metycaïne 0.01 Gm. ($\frac{1}{10}$ gr.) in physiological solution of sodium chloride.

Ampoules Metycaïne 2% and Epinephrine (1:25,000) 1 cc. Each cubic centimeter contains metycaïne 0.02 Gm. ($\frac{1}{50}$ gr.) epinephrine 0.04 mg. ($\frac{1}{2500}$ gr.) and thiourea 0.3% in Ringer's solution. The thiourea which is added to the dosage forms containing epinephrine in order to prevent oxidation complies with the following standards. It is a white, crystalline, almost odorless solid, soluble in water and hot alcohol and slightly soluble in cold alcohol, chloroform and ether. When 0.05 Gm. is dissolved in 10 cc. of water to which 2 drops of ferric chloride solution have been added, the color is only slightly augmented (*sulphocyanates*). Warm 0.05 Gm. of thiourea in a test tube until it melts, cool, add 10 cc. of water and 2 drops of ferric chloride solution; a blood red color results. Add 10 cc. of water and 4 cc. of diluted nitric acid to a mixture of 0.1 Gm. bismuth nitrate and 0.3 Gm. of thiourea and warm in orange colored solution results, which on evaporation yields crystals of an orange color. The melting point of thiourea ranges from 176 to 180 C.

Ampoules Metycaïne 2% and Epinephrine (1:50,000) 2.5 cc. Each cubic centimeter contains metycaïne 0.02 Gm. ($\frac{1}{50}$ gr.) epinephrine 0.02 mg. ($\frac{1}{5000}$ gr.) and thiourea 0.15% in Ringer's solution.

Solution Metycaïne 2% Metycaïne 2% in physiological solution of sodium chloride containing chlorbutanol 0.5% as preservative.

Tablets Metycaïne 0.15 Gm.

Metycaïne occurs as a fine white crystalline odorless powder. When applied to the tongue it possesses a slightly bitter taste followed by a sense of numbness permanent in the air, freely soluble in water about 1 in 1, soluble in alcohol and chloroform, insoluble in ether and olive oil. Its aqueous solution (1 in 10) is faintly acid to litmus. It is optically inactive. Metycaïne melts at from 171 to 173 C. From aqueous solutions alkali carbonates and hydroxides precipitate the free base as a water white to light yellowish oil which does not solidify at ordinary temperatures.

Dissolve about 1 Gm. of metycaïne in 10 cc. of water, separate portions of 2 cc. each, discharge the color of 1 cc. of diluted sulphuric acid and 1 cc. of potassium permanganate solution (distinction from *allylin* which gives a violet crystalline precipitate and soon disappears) gives a yellow precipitate with 1 cc. of gold chloride solution (distinction from *apofesine* which gives a lemon yellow precipitate) imparts a white changing to a yellowish and finally greenish yellow coloration

on the addition of 2 drops of diluted hydrochloric acid, 2 drops of a 10 per cent sodium nitrate solution and on gradually mixing with a solution of 0.2 Gm. of beta naphthol in 10 cc. of a 10 per cent sodium hydroxide solution, the color increasing in intensity as the concentration of the beta naphthol becomes greater (distinction from the *anesthetics responding to the diazo reaction* Warren, L. E. The Identification of Some Local Anesthetics, *J. A. Pharm.* 4, 12, 512). Dissolve about 0.1 Gm. of metycaïne in 1 cc. of sulphuric acid, the solution is colorless (*readily carbonizable substances*). Dissolve about 0.5 Gm. of metycaïne in 50 cc. of water, separate portions of 5 cc. each, yield no turbidity with 1 cc. of diluted hydrochloric acid and 1 cc. of barium chloride solution (*sulphate*), no coloration or precipitation on saturation with hydrogen sulphide (*salts of heavy metals*).

Dry about 0.5 Gm. of metycaïne accurately weighed over sulphuric acid in a desiccator for forty-eight hours, the loss does not exceed 0.25 per cent. Incinerate about 0.5 Gm. of metycaïne accurately weighed, the residue is not more than 0.2 per cent. Transfer about 0.25 Gm. of metycaïne to a 400 cc. beaker, add 100 cc. of water, followed by the addition of 25 cc. of tenth normal silver nitrate solution and 10 cc. of nitric acid, boil with continuous stirring and allow to cool in a dark place. Collect the precipitate of silver chloride on a Gooch crucible, wash with nitric acid and water followed by alcohol and ether, finally dry to constant weight at 105 C. The amount of hydrogen chloride calculated from the silver chloride found corresponds to not less than 12 per cent nor more than 12.35 per cent calculated to the dried substance. Transfer about 0.5 Gm. of metycaïne accurately weighed to a suitable Squibb separatory funnel, add 50 cc. of water, followed by the addition of 5 cc. of ammonium water, extract with seven successive portions of chloroform, using 35 cc., 30 cc., 25 cc., 20 cc., 15 cc., 10 cc. and 10 cc. respectively, wash the combined chloroformic solution with 15 cc. of water, filter through a pledget of cotton and evaporate to a thick oil in a stream of warm air, expose over sulphuric acid in a partially exhausted desiccator, dissolve the oily residue in about 10 cc. of previously neutralized alcohol, warm slightly, add 10 cc. of tenth normal hydrochloric acid solution, followed by the addition of an equal volume of water, determine the excess of acid by titration with twentieth normal sodium hydroxide solution using methyl red as an indicator, the amount of tenth normal hydrochloric acid solution consumed corresponds to not less than 86.5 per cent nor more than 88 per cent benzoyl γ (2-methylpiperidino) propanol.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
RAYMOND HERTWIG, Secretary

BOOKLETS 'GENERAL COMMITTEE DECISIONS ON FOODS AND FOOD ADVERTISING' AND 'RULES AND REGULATIONS (REVISED)'

Copies of the November, 1933, editions of the booklets General Committee Decisions on Foods and Food Advertising including all decisions adopted by the Committee up to date of issue, and the revised 'Rules and Regulations' will be furnished without charge on request addressed to the Secretary.

NOT ACCEPTABLE

NUTRO A HIGHLY NOURISHING NUT AND GRAIN FOOD

The Nutraventa Company, Battle Creek, Mich., submitted to the Committee on Foods a cooked mixture of roasted peanuts, wheat gluten, and sodium chloride (proportions not known) called "Nutro A Highly Nourishing Nut and Grain Food."

Analysis (submitted by manufacturer) —

	per cent
Moisture	61.5
Ash	1.2
Fat (ether extract)	8.4
Protein (N \times 6.25)	17.1
Crude fiber	0.8
Carbohydrates other than crude fiber (by difference)	11.0

Discussion of Label and Advertising—The label states that Nutro is 'A Healthful food' 'Good Food for Good Health' 'Nutro is a nut-grain food'.

Submitted advertising includes such claims as

The new health food prepared from choice nut meats and full cereal grains by a special process of intense cooking, 25 per cent more nourishing than meat, you may eat [it] to your heart's content and you will experience none of the harmful after effects caused by eating too much meat, you may eat all you want and still have no pimples or facial blemishes usually caused by over indulgence of your favorite meat, healthier than meat for it contains no poisonous bacteria, no uric acid, no ptomaine poison, it can't spoil, contains none of the tissue waste and uric acid found in meat, it is rich in vitamins, iron and all body building essentials and contains seven times as much lime as meat.

The advertising unjustifiably ascribes special health values to this ordinary peanut and wheat gluten mixture and falsely alleges that it is more nourishing and "healthier" than meat and that meat is harmful, producing "pimples or facial blemishes" containing "poisonous bacteria" uric acid and ptomaine poison." Meat is a wholesome food, just as wholesome as this product. It is incorrectly described as containing "choice nut meats and full cereal grains." "Full cereal grains" incorrectly imply the presence of whole grains. The product is not "rich in vitamins" (implying all the vitamins) or "all body-building essentials."

The company, in a letter of Aug 14, 1933 advises in a general way that new advertising will conform to requirements of the Committee and that it is not its "desire to put misleading advertising out to take advantage of the gullible and uninformed." The new label for the product, however carries the claims given above, which still indicate the intention of the company to promote the product as a special "health food." No one food provides or assures health or has special health values as implied by the designation "health food." Special "health food" advertising is thoroughly deceptive. No descriptive statement identifying the ingredients of the product accompanies the trade name, as required for accepted foods with fanciful trade names to prevent misleading advertising. The public is entitled to know the ingredients of the foods it consumes. The company did not respond to requests for copy of new advertising to demonstrate that former objectionable, deceptive advertising was no longer being used.

The company has ignored requests that it demonstrate that its present advertising complies with the requirements of the Committee for good advertising in the interest of the public as defined in the published Rules and Regulations and General Decisions of the Committee. The new label does not meet requirements for accepted food labels. This product will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG Secretary

CELLULOSE WAFERS

(SWEETENED WITH SACCHARIN)

Manufacturer—Chicago Dietetic Supply House, Inc., Chicago

Description—Wafers prepared from washed bran, commercially pure powdered cellulose mineral oil, India gum, sodium chloride, baking powder, sodium bicarbonate and saccharin (except when sold in states prohibiting the sale of saccharin in food).

Manufacture—Bran is washed with cold water until absence of starch is indicated by the iodine test. It is centrifuged to remove excess water and completely dried yielding coarse washed bran, which is ground and screened to produce fine washed bran.

The ingredients are mixed with the mineral oil in definite proportions. Boiling water is added to produce a soft dough which is rolled cut into wafers and lightly baked at moderate temperature until dry. The wafers are packed in wax paper in wax paper lined packages.

Analysis (submitted by manufacturer) —

	per cent
Moisture	3.4
Ash	4.4
Fat (essentially mineral oil) (ether extract)	28.8
Protein (N X 6.25)	4.0
Crude fiber	22.1
Available carbohydrates (calculated as starch—diastase method)	2.0
Unavailable carbohydrates other than crude fiber (by difference)	20.3
Calories—0.2 per gram 6 per ounce	

Claims of Manufacturer—For adding bulky indigestible residue to low carbohydrate diets.

- (a) ROSE OF TEXAS FLOUR (BLEACHED)
- (b) ROYAL FLOUR (BLEACHED)
- (c) SIN-RIVAL FLOUR (BLEACHED)

Manufacturer—Liberty Mills, San Antonio, Texas

Description—(a) and (b) Hard red winter wheat—blend of standard patent and first clear flours, bleached. (c) Hard red winter wheat first clear flour, bleached.

Manufacture—Selected wheat is cleaned, scoured, tempered and milled by essentially the same procedures as described in THE JOURNAL, June 18, 1932, p 2210. Chosen flour streams, such as are commonly used in standard patent and first clear flours, are blended and bleached with nitrogen trichloride (one-ninth ounce per 196 pounds).

CHILOCCO BRAND WHITE TABLE SYRUP

Distributor—Oklahoma-Kansas Wholesale Grocery Company, Arkansas City, Ark.

Packer—D B Scully Syrup Company, Chicago

Description—Table syrup, corn syrup base (85 per cent) with rock candy syrup (15 per cent) flavored with vanilla and coumarin the same as the accepted D B Scully White Crystal Table Syrup (THE JOURNAL, April 15 1933, p 1174).

BEECH-NUT STRAINED APPLE SAUCE

Manufacturer—Beech-Nut Packing Company, Canajoharie, N Y

Description—Sieved apple sauce retaining in high degree the natural vitamin and mineral values.

Manufacture—Spitzenburg and Red Spä apples are thoroughly washed, quartered and cored, and the stem and blossom ends removed. Weighed quantities in an air-exhausted glass-lined vacuum kettle with a small quantity of water are cooked in their own steam for fifty minutes, strained, processed and packed as described for Beech-Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p 1562). The processing is at 100 C for thirty minutes. Precautions are taken that the product does not contain significant quantities of lead and arsenic from arsenical spray residues on the apples used.

Analysis (submitted by manufacturer) —

	per cent
Moisture	87.1
Total solids	12.9
Ash	0.2
Fat (ether extract)	0.2
Protein (N X 6.25)	0.2

Crude fiber	0.5
Carbohydrates other than crude fiber (by difference)	11.8

Calories—0.5 per gram 14 per ounce

Vitamins and Claims of Manufacturer—See Beech-Nut Strained Carrots (THE JOURNAL, Nov 11 1933, p 1562).

PLEE-ZING FREE RUNNING TABLE SALT PLEE-ZING TABLE SALT

WITH 1 PER CENT CALCIUM CARBONATE OR WITH
0.7 PER CENT MAGNESIUM CARBONATE

Distributor—Plee-Zing, Incorporated, Chicago

Packers—International Salt Company, New York
Morton Salt Company, Chicago

Description—A table salt containing 1 per cent added calcium carbonate or 0.7 per cent magnesium carbonate which tends to preserve its free running quality the same as International Free Running Salt (THE JOURNAL, July 2, 1932, p 34) and Morton's Free Running Salt (THE JOURNAL, May 14 1932 p 1745).

NATIONAL BRAND UNSWEETENED EVAPORATED MILK

Distributor—The National Tea Company, Chicago

Packer—Dean Milk Company, Chicago

Description—Canned unsweetened evaporated milk, the same as Dean's Quality Evaporated Milk (THE JOURNAL Aug 6, 1932 p 477).

SATURDAY FEBRUARY 10 1934

INTERRELATIONS OF HORMONES AND VITAMINS

Biochemistry has directed attention to a growing number of substances which though present in or elaborated by the body in small amounts nevertheless may initiate striking changes. In activity they may outrank some of the most potent drugs such as still act on the body when they are administered in quantities as small as 0.3 mg. The potency of these types is such that measurements are being expressed in micrograms, that is thousandths of a milligram. The components of the internal secretions of the endocrine glands, often designated as hormones or autacoids, belong in this new category of superpotent substances as do the vitamins and the enzymes. Until recently knowledge of the structural chemistry of all these substances has been scanty, information as to the chemical mechanisms whereby they function in their varied specific ways is still slighter. When the chemical structure of each product is once firmly established, as it lately has been for vitamin C or ascorbic acid it will become possible and presumably customary to classify these substances according to their chemical make up.

For the present it is sometimes pointed out that vitamins as a class differ from hormones in that the former cannot be generated or synthesized by the animal organism. For its vitamins the body under normal conditions is dependent on extraneous sources, that is, food. The hormones may be endogenous as well as exogenous in origin. As hormones and vitamins have specific effects on the organism, the question has repeatedly been asked whether there is any interrelation between the two kinds of active substances. One answer is afforded by recent investigations of Aberle¹ at the Yale University School of Medicine. In common with earlier observers, she has noted the continued appearance of keratinized epithelial cells in the vaginal tract of several species that are subjected to a deficiency in vitamin A. This phenomenon is now familiar in the "cornified" vaginal smear.

One of the newly discovered gonotropic hormones that stimulate parts of the genital tract directly (rather than through the ovaries, as do the gonadotropic hormones) produces cells in the vaginas of spayed animals which are similar to those found in pregnancy. Both of these substances affect epithelial tissue in a definite manner but in each instance a different cell type is produced. Questions arise as to the interaction of the two: whether vitamin A and a gonotropic hormone each act directly and without regard to the presence or absence of the other or whether a gonotropic hormone can produce its characteristic action in an environment altered by the absence of vitamin A. Aberle has found that a placental extract standardized for its production of mucoid vaginal cells was incapable of producing any effect on the vaginal cells of rats subjected to A-avitaminosis. Control animals kept under identical environmental conditions and fed the same purified diet except for the addition of vitamin A invariably responded to the hormone by the production of mucoid vaginal cells. This shows that avitaminosis of A was responsible for preventing the characteristic action of a hormone. A unique interrelation of vitamin A and a gonotropic hormone has thus been established. Other instances in which avitaminosis of one sort or another interferes with the effectiveness of normal endocrine functions as expressed through hormone activity may be anticipated.

MENSTRUATION AND THE "SAFE PERIOD"

The biologic method of contraception, popularly known as the 'safe period' has been more or less generally discussed in newspapers and periodicals and is apparently the one technique short of complete abstinence that has thus far been free from criticism on religious and social grounds. From the point of view of medicine, psychology and esthetics there have been fairly well sustained criticisms against all the techniques thus far made available in various scientific works on the subject.

In this issue of THE JOURNAL (p. 452) Novak analyzes the scientific data offered in support of the idea that women with menstrual cycles approximating the four weekly type are not likely to conceive following exposures during a period up to eight days after menstruation begins and in the ten days preceding menstruation. To state the matter conversely, the maximum likelihood of conception is the period from the eighth or tenth to the eighteenth or twentieth day of the menstrual cycle with the maximum at about the twelfth to fourteenth days. In women with irregular cycles the problem is more difficult and less certain. The new evidence it would seem offers practical advice not only to those who wish to avoid conception but also to those who wish to overcome sterility, since it sets forth for them the optimal time in relationship to conception.

¹ Aberle, Sophie B. D. The Interrelation of a Gonotropic Hormone and Vitamin A. *Am. J. Physiol.* 106: 267 (Nov.) 1933.

Coincidentally with the publication of this article by Novak the *British Medical Journal* publishes the results of investigations by Wilfred Shaw,¹ who has made some interesting observations on this subject. The normal menstrual cycle is regarded as twenty-eight days, the first day of the period being considered the first day of the cycle. Dr Shaw studied the ovaries in thirty-six cases in which women with a twenty-eight day cycle were submitted to operation for various causes. In addition, he has collected forty-nine cases in which the uterus alone was removed. In twenty-one of the patients in whom the ovaries were examined, the uterus was studied histologically. In practically all of the cases examined for the presence of a ruptured follicle or a corpus luteum the evidence was clear that ovulation occurs on the fourteenth day of the menstrual cycle. There has been a belief among embryologists that ovulation can be provoked by coitus. Apparently most authorities are unwilling to accept this belief so far as it relates to the human being, although conceding its possibilities in animals in a lower scale.

The views of Novak, it seems, are in conflict with those of Shaw on the subject of anovulatory menstruation. Novak insists that sterility may at times be due to the fact that the woman who perhaps is menstruating normally and regularly and who is presumably normal in every other way is not giving off eggs. Shaw on the other hand, says

Much has been written in the last two years—in America—on so called anovular bleeding in women. It is not an exaggeration to say that almost all these publications are valueless with the evidence unreliable, discussion uncritical, and usually with the author's enthusiasm for the macaque's anovular bleeding outrunning his gynaecological discretion. Recently Novak has stated that, although he believes cyclical anovular bleeding in women to be more frequent than is generally believed he cannot yet produce the evidence. A more scientific method of approach would be first to produce the evidence and afterwards to judge the frequency of this form of haemorrhage.

Thus there is being developed scientific evidence to warrant the possibility that this method for the prevention of conception or birth control is sufficiently accurate to be dependable and at the same time psychologically, socially and esthetically sound. It calls obviously for a certain amount of civilized restraint. Conceding that complete abstinence is difficult to recommend and even more difficult to sustain the possibility of a brief period of abstinence should not be alarming. In view of the nature of the evidence now brought forward and rather well confirmed, it would seem to be desirable that large clinics especially interested in studying the prevention of conception might concentrate their efforts temporarily on a study of this method from all the different points of view that have been mentioned. The possibilities seem more promising than promoting the sale of various mechanical devices, chemical substances and other forms of intricate manipulation which have not met

any of the critical criterions that have been mentioned. The newer observations do not signify complete triumph. They do indicate the value of biologic and medical research and the necessity for further scientific study.

CONSERVATISM IN THE TREATMENT OF THROMBO-ANGIITIS OBLITERANS

The impression that the ultimate outcome in most cases of thrombo-angitis obliterans is the amputation of an extremity is rather prevalent. Indeed, the disease is described in some books as a progressive series of amputations. Many family physicians have thus come to believe that once the diagnosis is made a surgeon should be called to amputate the affected limb. That such an impression is erroneous is abundantly illustrated in the article by Samuels¹ in this issue of *THE JOURNAL*. In the last eight years he has treated by conservative methods more than 300 cases of thrombo-angitis obliterans and in only one was it necessary to amputate the leg. His percentage of amputation, therefore, is less than 1, whereas sponsors of other methods of treatment quote percentages many times larger. This article illustrates to what extent the gangrenous process may proceed and yet the life and limb be saved. In the conservative treatment of thrombo-angitis obliterans, attention to the minutest details are important. The affected limb must be maintained constantly in the horizontal position. Smoking must be prohibited. Injection of hypertonic sodium chloride solution intravenously should be started when the diagnosis is made and 300 cc given every other day until the gangrene and ulceration are healed. The dead tissue must be kept aseptic if possible and encouraged to slough. Pain should never serve as a valid excuse for amputation. Small doses of opiates may be necessary, but this is the exception. Sympathectomy and ganglionectomy, Samuels believes, have no place whatever in the treatment. The gangrene in thrombo-angitis obliterans is self limited and the only indication for amputation is total destruction of the foot, so that a weight-bearing stump is unattainable.

In doing physical examinations for peripheral arterial disease, the family physician should bear in mind that thrombo-angitis obliterans predominates in men between 18 and 45 years of age and rarely occurs in women and the victim is usually a smoker. Arteriosclerosis as a cause of arterial obstruction should be suspected in either men or women more than 45 years of age although if the patient also has diabetes he may be younger and the obstruction more extensive. Peripheral arterial obstruction should be suspected when there is fatigue of the lower extremities, coldness of the toes, burning in the sole of the foot after walking, and sharp pain in the buttock, which may simulate sciatica. Slight cyanosis of the toes may be observed, the nails

¹ Shaw, Wilfred. Ovulation and Menstruation. *Brit. M. J.* 1: 7 (Jan. 6) 1934.

¹ Samuels, S. S. Gangrene Due to Thrombo-Angitis Obliterans. *this issue* p. 436.

may be extremely brittle, and a difference may be noted in the hair growth. When the patient with both legs raised rapidly flexes and extends the feet, using the ankles as pivots, pallor of the plantar surface of the foot will soon be noted if there is arterial obstruction.

The diagnosis may be confirmed by the use of the oscillometer, an instrument that has been adapted to the use of general practitioners in conjunction with the sphygmomanometer. Conclusive signs of peripheral arterial obstruction are plantar ischemia, diminished temperature of the extremity and decreased amplitude of arterial pulses in the extremity as shown by the oscillometer. When complete health examinations include a survey of the extremities with reference to the condition of the arteries, many cases of incipient arterial disease will be recognized at a time when proper treatment will prevent the development of gangrene at some subsequent period.

EPIDEMIC MYALGIA, OR PLEURODYNIA

In 1856 and again in 1863 Finsen¹ in Iceland observed outbreaks of an epidemic disease, which he reported in 1874 as muscular rheumatism of the chest or pleurodynia. In the meantime a similar disease had been described in Norway by Daae² as an epidemic of acute muscular rheumatism spread by contagion. To Daae and then to Homann³ in Norway must be given credit for their early if not the first description in medical literature of this disease. In Norway the disease has been called the Bamle disease, from the place where the first case occurred. Daae's reports deal with 290 cases, all apparently transmitted by contact. A guest to a wedding came down with the disease and in a few days it appeared simultaneously in most of the homes of the other guests. The principal symptom was acute pain in the muscles of the chest, back and in some cases, the abdomen, with more or less marked febrile disturbances but with no indications of acute respiratory infection or of cutaneous eruption. The attack might last only two or three days. Relapses were common.

Since then the disease has been observed in other countries, including the United States, but the reports from this country show that the authors did not know anything about reports of outbreaks elsewhere. Dabney⁴ in 1888 described an outbreak in Virginia on the basis of the first twenty-nine cases, sixteen in students that came under his care. These cases all developed in the course of ten days. The sharp pain on inspiration or

movement gave rise to the term "devil's grip," which passed into popular use and even found its way into medical literature. Thirty-five years later a similar outbreak took place in the northeastern part of Virginia, which the newspapers called "devil's grip" and which is recorded by Payne and Armstrong⁵ as epidemic transient diaphragmatic spasm. Since then epidemics have been reported from New York,⁶ Philadelphia, Cape Cod⁷ and Tennessee.⁸ In a recent article, Small⁹ states that Dabney was the first to describe the disease and that the disease is not known outside this country. But epidemics have been recorded not only in Iceland and Norway¹¹ but also in England, Denmark, Sweden, Finland, Germany and Portugal. In Norway no less than 4,158 cases were reported in 1897.¹²

The latest and most extensive contribution to the description of the disease comes from Denmark. In 1930 Sylvest studied the disease on the Danish island of Bornholm, in some districts of which 10 per cent of the people were attacked. In current Danish literature the disease commonly is called "the Bornholm disease," but it has occurred elsewhere in Denmark, and 4,736 cases were reported to the health authorities in 1932. So far, knowledge of the disease has been based wholly on clinical observation. No reports have been published of postmortem examinations or of microscopic or bacteriologic study of the affected tissues. The clinical nosography, however, leaves hardly any doubt that the reports referred to in the foregoing deal with the same disease. In general the various epidemics seem to have been alike and to have differed from other epidemics. The epidemics occur almost exclusively in summer and early autumn, no age is exempt, though children between 5 and 15 years of age appear most susceptible, in adults the two sexes suffer alike. The disease seems to spread by contact but just how is not known. Insect transfer has not been established. Many authors, from Daae on, cite striking examples of spread by contact. Josephson,¹³ who describes a carefully studied outbreak on a training ship, tells that after a visit of the ship to an island several cases developed there, particularly in a restaurant frequented by the cadets. In families with several children, most of the children may be attacked, mildly or severely, at the same time. After a latent period of from two to four

days, pain on inspiration or other movements sets in abruptly in certain muscles, most frequently those in one or both hypogastric regions, or in the epigastrium, less frequently in the muscles of the chest, the back, the loins or the shoulders. The painful, aching muscles are tender on pressure. Sylvest particularly mentions that there may be definite, localized swelling and firmness in the affected muscles. When the muscles in the hypochondriac regions are involved, the upper abdominal reflex may disappear. On account of the pain on inspiration, breathing may be shallow and hurried. On walking, the patient may bend forward and toward the affected side. Hiccup may be present, suggesting involvement of the diaphragm. The attack is accompanied by comparatively mild febrile disturbances. The rule is that there are no pharyngeal or respiratory disturbances, no cutaneous eruptions, and "nothing abnormal in the internal organs." The only change in the blood is leukocytosis (with many eosinophils) in convalescence. The protozoan (*Plasmodium pleurodyniae*) described by Small¹⁴ could not be found by Wood, Sylvest or Josephson. The acute muscular pain may last from a few hours to twenty-four or more, but tenderness may remain for some time. Relapses are common (in one fourth of the cases, according to Sylvest), and one attack does not protect against a second attack later in all cases. In uncomplicated cases, recovery is usually prompt. Orchitis, otitis media, pneumonia and dry pleuritis may occur as complications. Petren¹⁵ reports twenty cases of orchitis in an outbreak of about 500 cases in Malmö, Sweden. In the diagnosis of the single case acute intra-abdominal conditions (especially when the pain is on the right side), acute coronary disease, influenza and herpes come into consideration, perhaps also dengue and pappataci (sandfly) fever where these diseases prevail. In the Malmö epidemic¹⁵ many patients were sent to hospitals as cases of appendicitis.

The true nature of the disease is unknown, and much remains to be done that may help to solve the problem. Examination of the affected muscular tissue by morphologic and microbiologic methods is still to be made. The question whether the disease spreads by direct contact or by insects demands close epidemiologic observation and perhaps also experimental investigation. In the meantime what shall the disease be called? Because it is epidemic and because muscular pain is the chief symptom, epidemic myalgia seems quite appropriate. The tenderness of the painful muscles, coupled with swelling at least in some cases, suggests an acute myositis, and if this proves to be the case on morphologic examination of suitable material epidemic myositis would be a still better name, pending the discovery of the cause of the infection.

BENZENE AS A CARDIAC AND VASOMOTOR POISON

Among the substances used in industry that carry serious hazards to health and life, benzene takes a more and more important place. In the rubber industry and in paints the properties of benzene as a solvent render its use extremely advantageous. But the volatility and toxicity of the substance render it, second only to lead, the most important of all modern industrial poisons. The effects of chronic benzene poisoning are well known: profound anemia due to destruction of red cells and injury to the hematopoietic system, hemorrhages due to decrease of clotting power, and loss of leukocytes with increase of liability to bacterial infection. In addition, acute poisoning by benzene vapor may induce convulsions. Now for the first time evidence has been brought forward by Dautrebande¹ showing that heart failure from ventricular fibrillation and collapse from paralysis of the vasomotor mechanism may also be induced by acute benzene poisoning. In his experiments Dautrebande has analyzed the problem of the acute effects of benzene on the circulation and has shown clearly that in addition to whatever influence benzene may have on the vasomotor centers it also exerts a paralyzing effect on the peripheral vasomotor apparatus, especially the nonstriated fibers in the walls of the smaller blood vessels. These observations throw the light of experiment on such fatalities as occur sometimes in painters who have used a benzene paint in a small unventilated chamber.

TRANSMISSIBLE LYMPHOMATOSIS (LYMPHATIC LEUKEMIA, LYMPHOSARCOMA) IN MICE

In mice, various forms of hyperplasia of the lymphocytes are not uncommon. Besides lymphocytic leukemia, neoplastic growths of lymphocytes, or lymphosarcoma, occur, frequently associated with blood involvement. These lymphocytic diseases in mice correspond closely to lymphatic leukemia and lymphosarcoma in man and certain other species. Furth, Seibold and Rathbone² recently published a report of their studies on the nature and transmissibility of the mouse disease. They conveniently designate all the forms of the disease as lymphomatosis. The disease is inoculable in healthy mice. Suspensions of lymphocytes from the blood or from lymphocytic tissue of lymphomatous mice are injected into the circulation or the subcutaneous tissue. In susceptible animals the same lymphocytes may produce leukemia or lymphosarcoma or both, depending on the place of inoculation and other variable factors. Apparently healthy mice vary in resistance to such inoculations. Roentgen radiation may destroy this

resistance, which seems to depend in some degree on hereditary factors. The search for a filtrable agent to account for the transmissibility of lymphomatosis has been unsuccessful. Cell-free plasma does not transmit the disease. Destruction of the lymphocytes by methods that do not affect viruses of various sorts prevents transmission of lymphomatosis. In other words, transmission is dependent on the transfer of intact lymphocytes. In this respect lymphomatosis of mice is different from leukosis of chickens, which like certain other tumors in chickens is caused by filtrable agents. The lymphocytes that transmit lymphomatosis are not merely immature lymphocytes but lymphocytes that in some manner not now understood have acquired the power of continuous multiplication far beyond physiologic control. This demonstration of the malignant nature of the lymphocytes in mouse leukemia lends support to the view that lymphocytic leukemia and allied processes in man are neoplasms in the strict sense. Further results from the valuable work by Furth and his associates will be awaited with interest.

Association News

THE CLEVELAND SESSION

Railroad Transportation to Cleveland

Information has been received that the Central the New England, the Southwestern the Western and the Transcontinental passenger associations have granted a rate of one and one third fares for the benefit of members of the Association who will attend the annual session to be held in Cleveland June 11 to 15.

In order to secure the reduced rate it will be necessary for members to have a CERTIFICATE to be endorsed by the Secretary of the Association and validated by a representative of the railroads at the Registration Bureau. These CERTIFICATES must be secured from railroad ticket agents at the time tickets to Cleveland are purchased. The CERTIFICATES when properly certified by the Secretary of the Association and validated by the agent of the railroads will entitle the holders to purchase return tickets, over the same route traveled to Cleveland at one third the regular fare. The reduced rate cannot be secured without a properly certified and validated CERTIFICATE.

MEDICAL BROADCAST FOR THE WEEK

National Broadcasting Company

The American Medical Association broadcasts on a coast to coast network each Monday afternoon from 4 to 4:15, Central standard time (5 o'clock, Eastern standard time 3 o'clock Mountain standard time and 2 o'clock Pacific standard time). There will be no broadcast on February 12 but the program will be resumed on February 19.

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45. The subject for Thursday February 15, is "The Modern Doctor." The speaker will be Dr. Walter L. Bierring, President-Elect of the American Medical Association.

Radio Talk from Station WBBM

The American Medical Association broadcasts on Tuesday mornings from 8:55 to 9 o'clock, Central standard time over Station WBBM (770 kilocycles or 389.4 meters). The subject for Tuesday February 13, is "The Health Examination."

ING TO THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GEN-
ERAL INTEREST SUCH AS REFERENCE TO SOCIETY ACTIVITIES,
NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Society News—At a meeting of the Ouachita County Medical Society in Camden, December 7, Drs. Herman W. Hundling and Lee Vallette, Parmer, Little Rock, spoke on "Acute Conditions of the Abdomen" and "Electric Shock," respectively. The Sebastian County Medical Society was addressed, December 12, by Drs. William R. Brooksher, Fort Smith, on "Radium Therapy in Medicine: Its Functions and Application," and Herbert Moulton, "Mikulicz's Disease." Speakers before the Sevier County Medical Society at DeQueen in December were Drs. Francis Walter Carruthers and Robert Caldwell, Little Rock, on "Diagnosis and Treatment of Otitis myelitis" and "Eye Injuries," respectively. The Saline County Medical Society sponsored a tonsil clinic, December 14, as a part of the county school health program.

CALIFORNIA

Los Angeles County Hospital Starts Operation—With the admission of a group of patients to the obstetric service December 12 the "acute unit" of the new Los Angeles County General Hospital began functioning. Nineteen stories high the building was constructed at a cost of \$12,000,000. Its bed capacity is 3,500. The maternity service is on the eighth floor.

Diphtheria Immunization Campaign—The health units of San Jose and Palo Alto and the Santa Clara County Health Department are cooperating with the public health committee of the Santa Clara County Medical Society in a "physicians' diphtheria prevention campaign." Material is provided without cost and the physician is making a charge of \$1 for its administration. No fee is charged for children of parents unable to pay. This is an attempt to abolish free immunization clinics it was stated.

Society News—A recent meeting of the Santa Cruz County Medical Society was addressed in Watsonville by Dr. Merrill C. Mensor, San Francisco, on industrial injuries. Dr. Henry A. R. Krutzmann, San Francisco, spoke on hypertrophy of the prostate before the Solano County Medical Society, December 5. Speakers before the Stanislaus County Medical Society recently were Drs. John H. Woolsey and Earl H. Gray, Woodland, on "Lesions of the Colon" and "Radiologic Studies of Fractures," respectively. The Tulare County Medical Society was addressed among others, December 10, by Dr. Frederic C. Bost, San Francisco, on "Practical Considerations in Fracture Dislocations of the Ankle."

DISTRICT OF COLUMBIA

University News—Dr. Arthur J. Cramp, director Bureau of Investigation, American Medical Association, Chicago, gave the fifth lecture in the series sponsored by the Smith Reed Russell Society of George Washington University School of Medicine, January 11, on "Patent Medicine and the Public or Pink Pills and Panaceas." Charles J. Stucky, Ph.D., research assistant in chemistry, New York State Psychiatric Institute and Hospital, New York, has been named professor of biochemistry at Georgetown University School of Medicine.

Anniversary of Carlos Finlay—Exercises commemorating the one hundredth anniversary of the birth of Dr. Carlos J. Finlay, who first advanced the theory that mosquitoes were carriers of yellow fever, were held in the Cuban embassy, December 3, under the auspices of the Washington chapter of the Pan American Medical Association, with Dr. Manuel Marquez Sterling, envoy of the Cuban government, acting as host. The program included addresses by Dr. Sterling, Senor Don Luis M. de Irujo, Spanish charge d'affaires, Col. Roger Brooke of the medical department, U. S. Army, Dr. Leland O. Howard, Brig. Gen. Jefferson R. Kean and Dr. Victor R. Alfaro.

FLORIDA

Personal—Dr. Robert L. Hughes, Bartow, was recently appointed a member of the state board of health, succeeding Dr. Leland H. Dame, Inverness, who became health officer of the Inverness district. Dr. Jorge A. Trelles, Tampa, has been appointed Cuban consul.

Society News—At a meeting of the Escambia County Medical Society in Pensacola, December 5, Drs Russell A Hennessey and Alfred D Mason, Jr, Memphis Tenn, spoke on "Nonsurgical Relief of Prostatic Obstruction," and James S Speed, Memphis, "Fractures of the Elbow Joints"—Dr Rosco G Leland director, Bureau of Economics, American Medical Association, Chicago spoke on medical economics before the Duval County Medical Society, Jacksonville, December 13

Public Health Meeting—Dr James R McEachern, Tampa, was elected president of the Florida Public Health Association, December 6 at its annual meeting in St Petersburg Jacksonville has been designated the place for the next annual session Speakers included the following

Dr Walter T Harrison U S Public Health Service Diphtheria Prophylaxis
Dr Estella Ford Warner, U S Public Health Service Child Hygiene
Carl E Buck Dr PH, New York American Public Health Association, American Conservation
Henry F Vaughan Dr PH, Detroit health commissioner Preventive Medicine from the Family Physician

ILLINOIS

Hospital News—Contract has been let for the construction of twenty one buildings at the Manteno State Hospital at an estimated cost of \$1,161,608 The new buildings will add 1700 beds to the capacity of the hospital, it was reported

Society News—At a meeting of the Stephenson County Medical Society in Freeport, February 12, the speakers will be Drs Harold S Diehl, Minneapolis, and Hugh Cabot Rochester, Minn on 'The Common Cold' and 'An Historical Survey of the Development of Operations for Prostate Obstruction' respectively—Speakers before the LaSalle County Medical Society in Streator, January 18, were Drs Carl B Davis and Frederick H Falls, Chicago, on "Anatomy, Symptoms and Treatment of Cervical Rib" and 'Premature Detachment of the Normally Implanted Placenta,' respectively—Dr Herman L Kretschmer, Chicago, gave a paper before the Peoria City Medical Society, January 16 on 'Modern Treatment of Prostatic Obstruction'—Dr Robert H Woodruff was among the speakers before the Sangamon County Medical Society in Springfield January 4, on "The Doctor and Vital Statistics"—Dr Thomas B Knox, Quincy addressed the Madison County Medical Society, Edwardsville, January 9 on 'The Doctor in the Medical Care of the Unemployed'

Chicago

Personal—Dr Eugene J Chesrow was decorated with the Order of the Crown of Italy, December 21 in recognition of his benevolent and charitable work among the Italians' of the city

Discussion on Medical Education—The General Trend of Medical Education and Practice will be discussed at a meeting of the Chicago Medical Society, February 14 Speakers will be Drs Walter L Bierring Des Moines, Iowa President Elect, American Medical Association Charles B Wright, associate professor of medicine University of Minnesota Medical School, Dean Lewis Baltimore and John H J Upham, Columbus Ohio, President and chairman of the Board of Trustees, American Medical Association, respectively Members of the faculty of Loyola University School of Medicine presented the program at the society's meeting February 7 Speakers included Drs Louis D Moorhead dean, Italo T Volini head of the department of medicine, Thomas P Foley clinical professor of medicine, Ralph C Sullivan, clinical professor of surgery, and Fred M Drennan clinical professor of medicine The society will not hold a meeting February 21

INDIANA

Cancer Meeting—Cancer was the theme of a special session in Shelbyville December 19 sponsored by several county medical societies, the Indiana University School of Medicine and a committee representing the American Society for the Control of Cancer The societies cooperating were for the counties of Shelby, Hancock Bartholomew Johnson and Rush Speakers included Drs Willis D Gatch dean of the medical school and Thurman B Rice of the state board of health In addition to talks the program consisted of motion pictures and an exhibit of specimens

Personal—Dr Max M Gutlin Bluffton has been appointed health officer of Wells County, succeeding Dr Francis M Dickson—Dr William O Hildebrand Topeka was named president of the Northeastern Indiana Academy of Medicine
